Compiled from the Bureau of Labour Statistics, Monthly Labour Review.

During 1910 the most important strikes occurred in the bituminous coal-mining industry and in the New York and Chicago clothing industries. On April 1, 300,000 miners went on strike to support wage demands. In most districts the operators soon granted the wage increases but 45,000 men remained out until September. The Columbus street railway employees struck in April, May and July because of discharges of union members.

In 1912 the textile strike at Lawrence, Massachusetts, and the anthracite coal strike were most important. The Lawrence strike lasted 9 weeks, affected 12 mills and involved 23,000 workers. A state law limiting the hours of work for women and children to 54 a week caused a reduction in wages against which the workers had struck. As a result of this strike 30,000 employees received wage increases of from 5% to 20% and increased pay for overtime. The unskilled workers received the largest increases. The

<sup>1</sup> It is not stated whether this is the number of workers directly affected, or the number directly and indirectly affected.

anthracite coal strike began March 31 1912, and lasted seven weeks. Some 170,000 workers went out. The strike resulted in wage increases, abolition of the sliding scale and establishment of a grievance committee. A strike in Paint Creek and Cabin Creek, W. Va., from April 1912 to July 1913 was marked by the loss of 13 lives. Its violence attracted much attention and the U.S. Senate ordered an investigation.

In 1913, 25,000 workers in the silk factories of Paterson, N.J., struck for shorter hours and increased wages. The strike failed. In September, the employees of the Colorado Fuel and Iron Co. struck for recognition of the United Mine Workers' Union, increased wages and observation of state mining laws. Both sides committed violence. John D. Rockefeller, Jr. at first declined to intervene. State troops were brought in and killed a number of strikers and members of their families. President Wilson then sent 2,000 Federal troops to restore peace. His proposal for settlement was accepted by the miners but rejected by the operators. After an investigation by the U.S. Commission on Industrial Relations, John D. Rockefeller, Jr., visited Colorado and instituted a system of employee representation; the workers were granted the basic eight-hour day and a check-weighman, but the union was not recognized.

In 1915 there were 102 strikes and six lockouts of machinists between July and October. In nearly every case the basic eight-hour day was gained. The coal strike in that year involved 350,000 men.

When the United States entered the World War in 1917 the American Federation of Labour discouraged strikes in the essential industries. A number did occur, however, and these were mediated by Government committees. On the whole the War period was one of industrial truce. During the War the greatest number of disputes occurred in the metal trades, building, clothing, textile, transportation and mining industries. In 1917 a very violent disturbance occurred in the mines at Jerome and Bisbee, Arizona. In July of that year 1,200 Bisbee strikers were loaded on cattle cars by armed citizens and transported across the desert to Columbus, New Mexico. Here they were taken over by soldiers and fed on army rations for three months, after which they scattered.

When the War was over the war labour adjustment boards were dissolved and workers, who had been prevented from striking by the promise of peaceful settlement, felt that the government and employers had broken faith. Some 176,000 employees struck in the clothing trades, 150,000 in the textile industry, 100,000 marine workers and 100,000 shipyard workers. The employers launched the "American Plan" of open shop and industrial unrest grew apace.

In Sept. 1919 the steel strike began as a result of the united action of 24 international unions. Some 365,000 men left their jobs but gradually they went back to work. By Jan. 1920 the remaining 100,000 men still out were sent back to work and the strike ended. In Seattle a general sympathetic strike with the shipyard workers, involving 60,000 people, was called and lasted from Feb. 6 to 11. The strike failed. In Aug. 1919, although forbidden by their national officers, 250,000 railway shopmen went on strike because of the delay of the Wage Adjustment Board to reach a decision on the demands of the men for increased pay. After six days the strike was called off and the men returned to work. At the request of President Wilson the demand for a wage increase was postponed to give the Government an opportunity to reduce the cost of living. In Nov. 1919, 435,000 bituminous coal-miners struck for wage increases of 60%, the six-hour day and the five-day week in order to distribute work throughout the year. An injunction was issued to prevent the use of union funds for strike benefits. In March 1920 an agreement was reached providing for a 27% increase in wages. In Sept. 1919, 93% of the Boston policemen struck for the right to organize and affiliate with the American Federation of Labour. Their places were filled with other men.

The coal strike of 1922 began on April 1, involving 600,000 men and effecting a complete tie-up of the central competitive (bituminous) field and of the anthracite industry. The operators

wanted the creation of a permanent arbitration board, and the union wanted the creation of a Government fact-finding commission and the continuation of collective bargaining. This, rather than wages, came to be the real issue in the anthracite strike. An agreement was reached on Sept. 2, providing for the continuation of existing wages and recommendation to Congress that a coal commission be appointed. The bituminous operators wanted district agreements, the union wanted a national agreement. The union demands included also continuation of existing wages, the six-hour day and five-day week. An agreement was reached Aug. 15, providing for cessation of the strike, and appointment of a joint committee to negotiate a wage scale to go into effect April 1 1923.

The strike of the railway shopmen began July 1, involving 500,000 men and constituted the most complete tie-up of that branch of the railway industry that the United States has ever seen. The shopmen struck primarily against the road's practice of contracting out work to non-railway shops and against the basic wage of \$800 a year established by the Railroad Labour Board. On Sept. 13 the unions and 50 railways signed an agreement which 126 roads signed by Oct. 27.

The most important strike in 1923 was that of 155,000 anthracite coal-miners in September for the check-off of union dues and a 20% increase in wages. The strike was settled after three weeks on a compromise basis, the miners securing a 10% wage increase. In May, 50,000 New York City clothing workers struck for a 10% wage increase. The strike lasted two weeks, embraced 2,000 shops and was won by the workers. The most important strike of 1924 was in the ladies' garment industry. On July 8, 50,000 workers led by the International Ladies' Garment Workers Union struck for an increase in wages, a 40-hour week and unemployment insurance. The strike lasted 13 days and was a success.

Industrial disputes were in general less numerous and less severe in 1925 than in any preceding year except the very quiet year of 1922. During the first half of 1925 some 720 strikes and lockouts involving 109,500 people took place. During the third quarter of the year 363 disputes occurred. The principal disputes were in the clothing, textile, building and coal-mining industries. The most important strike was that of 148,000 anthracite coal-miners which began Sept. 1, in a demand for a 10% wage increase, the check-off of union dues, two-year contract and complete union recognition. The strike lasted 170 days and covered the entire commercial anthracite area. An agreement ratified Feb. 17 1926 continued the terms of the previous contract, and set up a board of conciliation and other arbitration machines. The agreement is to be in force until Aug. 31 1930. New York dressmakers, numbering 30,000, struck on March 10 in 2,000 shops to enforce a provision in the joint agreement. The strike was novel in that the strikers reported at their places of work each morning and sat at their machines for six days without working. The strike was a success. (See INSURANCE, SOCIAL.) (J. R. Co.)

**STRINDBERG, AUGUST** (1849-1912), Swedish author (see 25.1038), died at Stockholm May 14 1912. His plays have been translated into English by E. and W. Oland (1912-3) and H. B. Samuel (1914).

See A. Henderson, *European Dramatists: August Strindberg* (1914); C. D. Marcus, *Strindbergs Dramatik* (1918); C. L. Schleich, *Erinnerungen an Strindberg* (1917).

**STRZYGOWSKI, JOSEF** (1862- ), Austrian scholar, was born at Bial, near Bielitz, March 7 1862. In 1892 he became a professor at Graz, and in 1909 was appointed professor of art at the University of Vienna. He wrote numerous works on art, dealing especially with Oriental influences on Western art (see BYZANTINE ART, 4.907; ROMAN ART, 23.475).

His works include: *Byzantische Denkmäler*, 1-3 (1891-3); *Hellenistische und Koptische Kunst in Alexandria* (1902); *Koptische Kunst* (1903); *Die bildende Kunst der Gegenwart* (1907); *Orsprung der Christlichen Kirchenkunst* (1920, Swedish and English trans.); Ed. *Early North European Church Art and Wood Architecture* (1925).

**STSHERBATSKY, FEDOR IPPOLITOVICH** (1867- ), Russian orientalist, was born at St. Petersburg (Leningrad) Sept.

19 (old style) 1867 of a family of old nobility. He was educated at Tsarskoye Selo, and studied philology at the St. Petersburg University, specialising in Sanscrit under Prof. I. P. Minajev. He graduated in 1889 and studied three years abroad, first at Vienna under Prof. G. Bühler, then in Bonn, under Prof. H. Jacobi. In 1904 he became professor of Indian literature at the St. Petersburg university, and in 1916 was elected member of the Prussian Academy of Sciences. The years 1910-1 were spent in British India for scientific research. His knowledge of Tibetan languages and of Buddhism enabled him to enter into friendly relations with the leading Buddhist priests. He was invited to meet the Dalai-Lhama, with whom he had several interviews without any interpreter. His thorough understanding of Buddhism makes his work, *The Theory of Knowledge and Logic according to the Later Buddhists* (1899), a most valuable book (German translation, 1924). He has published many Sanscrit MSS. in the *Bibliotheca Buddhica* of the Academy of Sciences. In 1923 the Royal Asiatic Society published his work, *The Central Conception of Buddhism*, and in 1926 was published *The Conception of Nirvana*.

**STURDEE, SIR FREDERICK CHARLES DOVETON** (1859-1925), British sailor, was born at Charlton, Kent, June 9 1859, and entered the navy in 1871. He was promoted lieutenant (1880), commander (1893), captain (1899), rear-admiral (1908), vice-admiral (1913), admiral (1917) and admiral of the fleet (1921). He saw service in Egypt (1882) and in Samoa (1899), when he was in command of the Anglo-American force. He was assistant director of naval intelligence to the Admiralty (1900-2) and chief of staff, Mediterranean Fleet (1905-7) and Channel Fleet (1907). In 1910 he became rear-admiral of the first battle squadron, and commanded the 2nd cruiser squadron (1912-3). During the World War Sturdee was made chief of the war staff in Nov. 1914. As commander-in-chief in the South Atlantic and Pacific, he led the squadron which won the battle of the Falkland Is. Dec. 8 1914, and he was in command of the 4th battle squadron when it took part in the battle of Jutland. He was created K.C.B. in 1913, K.C.M.G. in 1916, and a baronetcy was conferred on him in 1916, with the title "of the Falkland Is." From 1918-21 he was commander-in-chief at the Nore. He died May 7 1925.

**STURDZA, DEMETRIUS** (1833-1914), Rumanian statesman (see 25.1051), died at Bucharest Oct. 21 1914.

**STÜRGKH, CARL, COUNT** (1859-1916), Austrian politician, was born at Graz Oct. 30 1859, of an ancient noble Styrian family, and in 1881 he became an official of the Statthaltereie at Graz, and later of the ministry of education. He left the state service in 1891, when he was elected as a representative of the loyal landholding interest to the Reichsrat. He attached himself to the Left of the German party, and came forward as a keen opponent of universal suffrage. He was from Feb. 10 1909 to Nov. 3 1911 minister of education, and a zealous advocate of the humanistic education traditional in the gymnasia. On Nov. 3 he became Prime Minister. Stürgkh was one of the committee of five ministers who decided on the dispatch of the ultimatum to Serbia and the declaration of war, which brought on the World War. He was killed on Oct. 21 1916 by a shot fired by the Social Democrat Freidrich Adler, a son of the Social Democrat leader, Viktor Adler, as a protest against Stürgkh's government without parliament (see AUSTRIAN EMPIRE).

**ŠTURSA, JAN** (1880-1923), Czech sculptor, was born at Nové Město in Moravia. In 1899 he entered the Academy of Fine Arts at Prague as a pupil of Myslbek. His early works manifest the influence of the symbolic literature of that period, but by 1905-7 he had already attained an individual expression in such works as "Puberty" (1905), "The Melancholy Girl" (1906) and "Primavera" (1907). A journey to Italy in 1907 was the opening of a new epoch in his creative work. He was captivated first and foremost by the warm magic of femininity which is manifested in "Eve" (1908, State Gallery, Munich), "Hetaïra" (1909), "Messalina" and the monumental representation of the dancer "Sulamith Rahu" (1911), now in the gallery at Venice. At the same time he interpreted the oppo-

site feminine type, the intellectuality of which is incorporated in the monument to Hana Kvapilova (1912), the famous Czech actress. During the same period Štursa produced the group of statuary for the pylons of the Hlavka Bridge at Prague. In 1916 he was appointed professor at the Academy of Fine Arts in Prague, and it was in this period of his artistic maturity that he created the "Wounded Man." He also produced a number of portrait busts, the most noteworthy of which is that of President Masaryk. The leader of the modern school of Czech sculpture, he died in 1923.

**STURZO, LUIGI** (1870- ), Italian priest and political organiser. Born at Caltagirone, Sicily, on Nov. 26 1870, he entered the priesthood at an early age, but soon took to politics and showed from the first a marked ability in creating diocesan committees, co-operation unions, etc., and guiding the masses in the direction of Christian democracy. He was practically unknown outside his native province, until on the outbreak of the War, he came to Rome as secretary of the *Azione cattolica*. After the Armistice he was chosen political secretary of the *Partito Popolare italiano*, founded early in 1919. There had been a political Catholic movement in Italy even before the War, but it was due to the organising genius of Don Sturzo that the *Partito Popolare* made such rapid progress in so short a time. The general tendency of the party was Christian Socialist, and Don Sturzo advocated social reforms of a radical nature, especially in agriculture, as the majority of the party's adherents were peasants; unlike the Socialists, he demanded the expropriation of the land with compensation for the landlords, collaboration of capital and labour in industry and a patriotic foreign policy.

But an extremist wing, led by Sig. Miglioli, soon arose, and Don Sturzo, although mildly critical of its Bolshevik methods, never definitely disowned it. At the elections of Nov. 1919, thanks to the proportional system introduced by Nitti, the *Partito Popolare* secured 101 seats, and subsequently, by holding the balance between the various parties, became a dominant force in Italian politics. When Sig. Bonomi was trying to form a Cabinet after the fall of Giolitti in Feb. 1922, it was Don Sturzo who dictated its composition to him and became his *éminence grise* after it was constituted. In the early days of Fascism Don Sturzo did not oppose it, although there were frequent affrays between the black-shirted *squadre* and the Migliolini. After the march on Rome he allowed several Popolari to enter the Cabinet, but his half-hearted support of the Mussolini Govt. resulted in their withdrawal, and Don Sturzo and his party definitely joined the opposition. A section of the party, having remained faithful to Sig. Mussolini, broke away from the *Partito Popolare* and constituted the *Centro nazionale cattolico*. Don Sturzo's activities had, however, brought him into disfavour with the Vatican, which, after issuing a general admonition to priests not to mix themselves up with party politics, hinted that he would be well advised to leave Italy. He consequently went to England and France. In 1925 he published *Pensiero antifascista*. (L. V. \*)

**SUBMARINE.**—The first practical submarine was constructed by David Bushnell in 1775, and his ideas were revived some 25 years later by R. Fulton, who constructed a boat called the "Nautilus," driven by means of a hand-worked screw and fitted with a copper vessel containing compressed air to give a reserve supply for breathing. This air enabled the boat to remain under the water for about four hours. The vessel actually descended on trial to a depth of 25 ft. and placed a torpedo underneath a ship.

#### THE SUBMARINE BEFORE THE WORLD WAR

*American Civil War.*—The first vessels to take part in actual warfare were of a type known as the Davids, built by the Confederates during the American Civil War. These were small iron boats propelled by hand from four to seven knots and armed with a spar torpedo bearing about 50 to 70 lb. of powder. One of these, manned by nine men, attacked the Federal warship "Housatonic" and sank her, but was herself sunk by the wave thrown up by the explosion. About 1860, the submarine boat

began to slowly develop from the crude form propelled by manual labour to a power-propelled vessel, which could be considered a factor in naval warfare. In 1863 the "Plongeur," 146 ft. long, 12 ft. in diameter, and propelled by an 18-H.P. compressed air engine, was built in France.

*The "Holland" Type.*—A very important type was constructed in 1877 by Mr. Holland, which was propelled by a petrol engine. For the purpose of diving, water was admitted into internal ballast tanks until the boat had a small positive buoyancy, immersion being maintained by the use of horizontal rudders. The importance of this type is due to the fact that the first submarines for the British Navy were based on Mr. Holland's ideas. The following are a few of some of the other types of submarines built by the various naval powers round about this period.

*Russian Boats.*—In 1881, M. Goubet constructed several submarines for the Russian Govt., 16½ ft. long, of oval section, 5½ ft. by 3½ ft. amidships, tapering to a point at each end. The boat was manned by two persons only, and all valves and other mechanism were brought within reach of the two operators in order that no movement which might upset the trim of the boat was necessary. The power for driving the screw propeller was obtained from an electric motor driven by accumulators, and submersion was effected by admitting water into ballast tanks, this water being expelled by a pump when the boat was required to be brought to the surface again.

*Construction in U.S.A.*—In 1887 the United States of America invited designs for submarines, and after careful consideration of all those submitted the Holland design was accepted and formed the basis of the designs for the "Plunger," the "Holland" and the six vessels of the "Adder" Class. The latter were single screw boats, 63 ft. long, 104 tons surface displacement and were driven on the surface by petrol engines, giving a speed of about 8½ knots. When submerged, an electric motor supplied from accumulators was used, giving a speed of seven knots. They were armed with one bow torpedo tube and carried five torpedoes, and, as in the original Holland design, they were submerged by admitting water into internal ballast tanks and then dived by the aid of horizontal rudders.

Another interesting type was the "Narval" design by M. Laubeuf and constructed in 1899. She was 112 ft. long, 12 ft. 4 in. beam, displaced 104 tons, and had a surface speed of 11 knots and eight knots submerged. The machinery was a triple expansion steam engine, obtaining steam from a water tube boiler burning petroleum. This formed the motive power for surface propulsion and also the power for driving the dynamo for recharging the accumulators, which furnished the power in the submerged condition. The vessel had a double hull and was submerged by admitting water into the space between the inner and outer hulls, control in the horizontal and vertical directions being effected by rudders fitted forward and aft.

*Great Britain.*—In 1900 five "Holland" type boats were ordered for the British Navy, which were practically identical with the boats of the American "Adder" class previously mentioned. After experience with these, 13 boats of an improved design were laid down in 1902 and known as the "A" class, followed by 11 boats of the "B" class, completed between 1905 and 1906, and then 38 of the "C" class, completed between 1906-10. All these boats were armed with two torpedo tubes, and all except the A.13 were driven by petrol engines on the surface and electric motors when submerged. The A.13 was fitted with heavy oil engines for surface propulsion.

In 1907, the first of a larger and improved type, known as the "D" class, was laid down, particulars of which were as follows: length 162 ft., breadth 20 ft. 6 in., draft 11 ft., surface displacement 500 tons, submerged displacement 620 tons; horsepower on the surface 1,200 H.P., submerged 500; speeds 14½ to 15 knots on the surface and nine to 10 knots when submerged. This "D" class immediately preceded a somewhat similar type of vessel, which formed a very large proportion of the number of submarines in the British War flotillas.

In these vessels a more radical departure from the parent

Holland type was made than in the "A," "B" and "C" classes, main ballast tanks being introduced on the outside of the main circular pressure hull. The hull shape was modified by the adoption of twin screws driven by vertical four-cycle Diesel engines instead of the single screw driven by horizontal petrol engines in the previous boats, the disposition of the twin bow torpedo tubes vertically instead of horizontally, and the provision of a stern torpedo tube. These departures from the previous type were made with the objects of increasing the endurance of the boats at sea and of eliminating the risks attending the use of petrol. The external tanks enabled the reserve of buoyancy to be increased, thus rendering the boats less liable to founder suddenly in case of collision or similar accident, and making them more habitable at sea.

A 12-pdr., on a mounting which was housed inside the superstructure and operated by compressed air so as to pass rapidly from the firing to the housing position, was installed in "D4" and was the first instance of the mounting of artillery on a submarine. Up to this time the British submarines only had torpedo tubes forward and aft, but a demand arose in the fleet for broadside tubes, and to meet this demand the "E" class was designed for the 1910-1 programme. The provision of the two broadside tubes in the "E" class was the chief cause of the difference in dimensions between this class and the "D's," but of course this increased size had its natural concomitant in increased power, speed, habitability and endurance. In the first "E's," one bow tube only was fitted, owing to reports against these tubes having been received, but in the later "E's" of the 1911-2 programme the two bow tubes were again fitted. This class also was the first to have the main hull sub-divided by transverse bulkheads, thus increasing the safety of the boats in case of accident, and also increasing the strength of the hull against external pressure.

These vessels proved themselves a very suitable and reliable type in many ways. Two of them, A.E.1 and A.E.2, proceeded under their own power to Australia and took up duties with the Australian navy. One of them had over 30,000 m. to her credit before it was necessary to refit the propelling machinery. As seagoing boats they were a distinct step in advance of previous classes. The extensive superstructure, combined with the navigating bridge built over the conning tower, made them easy to navigate in even the roughest weather. This advantage is the more appreciated when it is understood that only in the finest weather could a "B" or "C" class boat cruise on the surface with open hatches. The overall length of the "E's" was 181 ft., beam 22 ft. 7 in. over the side tanks, and the displacement when submerged was 780 tons. The torpedoes carried were 18 in. in diameter, and a spare torpedo was carried for each tube, making eight torpedoes in all for the original "E's" and 10 for the later boats. A 12-pdr. gun was also carried.

The endurance at a cruising speed of 10 knots was 2,650 naut. m. on 45 tons of oil. A surface speed of 15 knots was obtained, the power being provided by two Vickers heavy oil engines, each of 800 brake horsepower. The motors for use when submerged each developed 420 b.h.p., giving a speed of 10 knots. The power for the motors was provided by two separate batteries, each of 112 cells. Air storage was provided by 57 bottles stowed about the ship, the bottles being charged by high pressure air compressors. To equip these boats for more effective scouting and patrol work a wireless installation was fitted, the aerial being carried on folding masts. In addition, a set of under-water signalling gear was fitted. Two periscopes were carried, one being a simple single power instrument, the other being arranged for use with varying powers and also for use as a "sky searcher" for detecting aircraft.

Another type of submarine with a complete double hull was developed by Messrs. Vickers, and four of these boats were ordered and called the "V" class. These were 147 ft. 6 in. over all, beam of outer hull 16 ft. 3 in., and submerged displacement 460 tons. The speeds were 13 knots on the surface and 8½ knots when submerged, the armament consisting of two 18-in. bow tubes. The "G" class followed upon the Vickers design and was

## TYPES OF MODERN SUBMARINES

FIG. 1. H.M. Submarine L. 16. (Great Britain). FIG. 2. H.M. Submarine M. 3. (Great Britain). FIG. 3. H.M. Submarine X. 1. (Great Britain). FIG. 4. Fleet Submarine V. 1. (United States).

(Figs. 1, 2 and 3. Photographs by Abrahams & Sons, Devonport. Fig. 4. Courtesy of U.S. Navy Dept.)

of increased dimensions and displacement, being 187 ft. long, 22 ft. 8 in. beam and a submerged displacement of 970 tons. The "G's" dimensions followed the single hull "E" class very closely but with increased displacement, consequent on the provision of the double hull. Their full surface speed was 14-15 knots, obtained by twin heavy oil engines, each of 800 brake horsepower. Submerged, the speed was 10 knots with 2 motors each of 420 brake horsepower. The armament was two bow and two broadside 18-in. torpedo tubes and one stern 21-in. tube, with, in addition, two guns mounted on the superstructure, one being a disappearing 3-in. "Q.F." type and the other a 2-pdr. "H.A."

#### THE SUBMARINE DURING THE WAR

*World War Construction and Types.*—In the early months of the World War a large number of "E" boats were ordered, in addition to some to the design of the Electric Boat Co. of America. The first batch of these latter, known as the "H" class, were built at Messrs. Vickers' Canadian establishment at Montreal, and later, more were built by Messrs. Vickers at their home works to a slightly modified design to enable them to carry a heavier armament. These were 171 ft. 9 in. long, 15 ft. 9 in. beam, and of 510 tons submerged displacement. The speeds were 13 knots on the surface and 10 submerged. The chief feature in this class was the very powerful torpedo armament carried in relation to their size, four 21-in. torpedo tubes being arranged in the bows and six torpedoes carried.

Another interesting type of submarine was the "J" class, the first of which were ordered at the beginning of 1915. These were the fastest internal combustion engined boats in the world, since they obtained a speed on the surface of over 19 knots. They were of the double hull type, 275 ft. long, 23 ft. beam and 14 ft. draught, displacing on the surface 1,210 tons, and when submerged 1,820 tons. For surface propulsion three sets of oil engines were fitted, giving 3,600 S.H.P. The horsepower for submerged propulsion was 1,350. Four bow and two broadside tubes were fitted for firing 18-in. torpedoes, and in addition one 3-in. or 4-in. H.A. gun was mounted.

As the submarine requirements during the World War of the main fleet increased, it became necessary to have a type which, whilst still retaining the ordinary functions of the submarine, could yet maintain station with the fleet when cruising. This involved a higher speed on the surface than the "J" class, and the necessary requirements were embodied in the design of the "K" class. These vessels had a submerged displacement of 2,560 tons and a surface displacement of 1,880 tons. They are 338 ft. long overall with a beam of 26 ft. 6 inches.

The double hull principle is embodied in a modified form, the ends of the boat, which might be damaged without endangering its immediate safety, having only a single hull at the sides. The speed was 24 knots, the power being obtained from twin sets of geared steam turbines developing a S.H.P. of 10,500, the steam being obtained from two Yarrow boilers. The funnels were arranged to hinge down when preparing to dive, and water-tight hatches covered the funnel openings as the latter hinged back. The turbine machinery was supplemented by an 800 B.H.P. heavy oil engine, coupled up to a dynamo. This arrangement enabled the turbines to be reserved for higher speeds only, whilst the dynamo, in addition to charging the batteries, supplied the main motors with power for cruising at economical speeds. Submerged, the speed of these vessels was nine knots.

The turbines are installed in a separate compartment, water-tight bulkheads being provided at the forward and aft ends of the compartment, with two doors in the former, one for access to the boiler room and one to the main passageway to the fore part of the vessel, and one in the latter for access to the motor room. The boiler room contained, in addition to the boilers, feed and oil pumps, heaters and filters, and forced draft fans, the latter driven by impulse steam turbines. The hinged funnels are lowered and the opening closed simultaneously by means of an electric or hydraulic motor and similar covers for the boiler room air vents are also hydraulically operated.

Additional protection for the navigating officer and quartermaster was provided in the form of a deck house built over and around the ordinary conning tower. The periscope fittings were the longest fitted up to that time, being 30 ft. from eye-piece to head-piece. Another important accessory was the long-distance wireless installation, the aerials being carried on telescopic masts, enabling the commanding officer to keep in touch with his base when operating a very great distance from it. A telemotor system was installed for raising the periscopes and telescopic masts, and also for working the ballast tank vent valves, and the introduction of this hydraulic power for such operations made such large submarines a practical proposition. The armament of this class was four bow and four broadside 18-in. tubes, with a spare torpedo for each tube, and in addition three guns, two 4-in. and one 3-in., for high angle work. These vessels were self-contained units of the fleet and did not rely on a parent ship as in the case of the "E" and other classes.

*Further Developments.*—As the War progressed it became necessary to add more submarines to the fleet, and the first of the "L" class, the design of which was based on the very successful "E's," was ordered towards the end of 1917. These combined the best qualities of the previous boats with an increased speed over that of the "E" class. (See Plate, fig. 1.)

The circular single hull was used with the side ballast tanks as in the "E" class, and in the first design for these boats the stern was wedge shaped, as in the "E" and "H" boats, but a second design had an improved duck stern, like the "J" and "K" classes. The length extreme is 231 ft., the beam near the side tanks 23 ft. 6 in., and the total submerged displacement 1,070 tons, with a surface displacement of 890 tons; 12-cylinder oil engines, developing a total B.H.P. of 2,400, gave, with twin-screws, a speed of 17½ knots on the surface, and the submerged speed, with a total B.H.P. of 1,600, was 10½ knots. The torpedo equipment in this class consisted of four 18-in. or 21-in. tubes in the bow and two 18-in. in the broadside room, with a spare torpedo for each tube. A 4-in. gun was mounted on the superstructure just forward of the bridge and conning tower. A novel feature was the night periscope fitted, which enabled the crew to keep a more effective watch at night.

*The "M" Type.*—Another outstanding type of boat was the "M" class, which were really submarine monitors built to carry a 12-in. gun. They were of the double hulled type, 296 ft. long, 24 ft. 6 in. beam, and with a draught of 15 ft. 9 in. had a displacement on the surface of 1,600 tons, becoming 1,950 tons when submerged. The speeds were 16 knots and 9½ knots on the surface and submerged respectively, the horsepower of the machinery being as in the "L" class boats. In addition to the 12-in. gun a 3-in. H. A. gun was carried, and the torpedo armament consisted of four 18-in. bow tubes. Only three of these boats were completed, the last being delivered from Messrs. Armstrong's, the builders, in Oct. 1920. (See Plate, fig. 2.)

*The "R" Class.*—The "R" class, ordered late in 1917, were small vessels of single hull type, as the original Holland boats, built as a "submarine destroyer of submarines" or "contre-submarine type." Their outstanding feature was that, unlike all other submarines in the world, they were faster below the water than on the surface. The speed submerged was 15 knots with 1,200 H.P., and that on the surface was 9½ knots with 240 H.P., the armament consisting of six 18-in. bow tubes. These boats were intended to submerge and chase the German U boats and use their six bow tubes by salvo in order to destroy them. Only two of these vessels were in the service in 1926.

*Minelayers.*—Another type developed under the stress of World War requirements was the minelaying submarine, and several of the "E" and "L" classes were equipped for this service. The mines were loaded into vertical tubes, which passed through the external tanks, and mechanical gear was fitted for locking the mines in position and releasing them when required.

*Performances.*—The K26, a boat built to an improved "K" design, completed in 1923, undertook a world voyage in 1924. She left Portsmouth on Jan. 2 1924 for Gibraltar and Malta, arriving on Jan. 14. After the fitting of special ventilating

arrangements, she continued her passage through the Red Sea and thence to Colombo and Singapore, at which places she arrived respectively on April 29 and May 14. Leaving Singapore on June 10, she arrived in England at Portsmouth on Aug. 26. At the time of this cruise the K26 was the largest and heaviest submarine in service in any navy. Since then, however, further developments have been made in large submarine design, the X7 holding pride of place as the largest submarine in the world in 1926, her dimensions being as follows:—

Length 350 ft., beam 29 ft., 10 in., draught 17 ft., surface displacement 2,525 tons, submerged displacement 3,600 tons. The cost of this vessel, excluding the armament, is estimated at about £950,000.

The original British Holland boats particulars were as follows: Length 63 ft., beam 11½ ft., surface displacement 104 tons, submerged displacement 120 tons.

*France.*—In the early stages of the submarine, France displayed greater originality, due to the fact that in that country there was a strong school of thought which even then considered that the vessel would drive surface war vessels from the

seas. In 1910, the "Gifford," the last of the famous "Pluviose" type of submersible, was launched, the "Pluviose" having been launched in 1907. There were in all 34 boats of this class built, the earlier vessels being steam propelled and the later by Diesel engines. This type was designed by M. Laubeuf and was of particular interest, since the original German U-boats were copied from the Laubeuf design and clearly showed their parentage even in their latest stage of development. The development reached as regards vessels launched or completed about this time is shown in Table I.

From this stage onwards the development of the vessels of all nations followed similar lines to that of the British boats already described, the desire for heavier armaments, greater endurance and improved seagoing powers leading to larger dimensions with the concomitant increase in displacement and horsepower of machinery, and this normal process of evolution continued until the beginning of the World War in 1914.

*Germany.*—The next most important naval Power during the World War was Germany, who made her supreme effort on the sea with the submarine. There were at least seven distinct types laid down during the War period by the Germans, each type being divided into various classes. The modifications to the parent type producing these classes were brought about by War experience. The types were as follows:—

1. The ordinary U-boat, 2. the UA cruiser or UK type, 3. the UB or coastal type, 4. the UC or small minelayer type, 5. the UE or larger minelayer type, 6. the UF or Flanders coast defence type, and, 7. the converted Deutschland type.

The particulars of these various types and the subdivision into classes are shown in Table II.

Of the UF or Flanders coast defence type about 80 were ordered, but none were ever completed, and it is possible that the bottling up of Zeebrugge and other ports by the British navy rendered the boats useless for their intended purpose and caused their construction to be stopped. They were generally similar in design to the medium UB type shown in the preceding table. The boats of the Deutschland type are of especial interest, since they were originally designed as submarine mercantile vessels. Further details of these German submarines are given in a paper read by Mr. A. W. Johns before the Institution of Naval Architects, London, in March 1920, and of the profile and sectional views of types of U-boats (see figs. 1a and 1b) are reproduced by permission from that paper.

*Washington Conference.*—The construction of submarines was considered, together with that of other war vessels, by the Washington Conference in 1922, and it was proposed on behalf of Great Britain that submarines should be abolished by all nations. Lord Lee, the then First Lord of the Admiralty, contended that the submarine could not be regarded as a defensive weapon because the War had shown it was unable to disturb large groups of naval units, it was impotent against a big naval attack, could not stop the transport of large masses of troops and, finally, was suitable only as a weapon of offence against merchantmen. Almost all the other Powers, however, were in favour of the retention of the submarine and the proposal was consequently not adopted.

After the Conference, therefore, it was only natural that the nations should turn again to the consideration of submarine construction, and the trend of design (see Plate, fig. 4) is shown by Table III. of the vessels launched or laid down since 1923.

**SUBMARINE CAMPAIGNS.**—The submarine was a new weapon of as yet unknown capabilities in Aug. 1914 when the World War broke out. The British had some 56 submarines of varying ages, the 18 newest boats of the D and E classes being grouped in the 7th Flotilla and based on Harwich. In charge of the whole submarine service was Commodore Roger Keyes who also took an active part in their operations. The 7th Flotilla was used throughout the War mainly in keeping a more or less continuous watch on the mouths of the German rivers and in other places where German warships might be expected. The A and B classes were fit only for coast defence. The C class which could keep the sea for a few days guarded the Forth, the Thames and the Straits of Dover.

Germany, in Aug. 1914, had 28 submarines of which the first batch, U1 to U18, had an unsatisfactory type of engine and could be relied on only for short voyages or for guard duties near home. U19 to U28 were able to make longer journeys, but to what extent was as yet unknown either to Germany or to England.

### I. THE OPENING PHASE

Both belligerents, at the outset, had the same ideas as to the method of employment of a submarine in War; it was to be used for attacking warships. It carried no guns since it could not use them without coming to the surface to fire; and its only armament consisted of torpedoes to be discharged when the boat was submerged.

*Campaign of 1914.*—It was expected by the German Naval Authorities that, on the declaration of War, the British Navy would immediately appear in Heligoland Bight to make an attack in force; the submarines were therefore sent to defence stations to meet the impending attack. When, after two days, no British ships appeared, the German command determined to attempt to locate them and 10 U-boats proceeded to the North Sea on Aug. 6, sweeping in line abreast. This was the first time so many submarines had acted as a squadron, and much was hoped from the operation; but only 8 boats came back, and they had little to report. One boat, U15, had seen some of our cruisers, only to be cut in half by the "Birmingham." Of the fate of the other lost boat, U13, nothing definite is known. The reconnaissance had proved too costly; a squadron attack by submarines was not repeated, and thenceforth the U-boats operated singly. Further attempts were made throughout Aug. to find the British main fleet; when these also failed, the German command definitely decided to abandon submarine operations against the Grand Fleet, and use the boats in attacking smaller men-of-war than capital ships. The first submarine success of the War was achieved by Hersing, who in U21 on Sept. 5 sank the light cruiser "Pathfinder" off St. Abbs Head. A week later Horton in E9 sank the light cruiser "Hela" in Heligoland Bight, with the result that the High Sea Fleet abandoned the Bight as an exercising ground. The most resounding event of the campaign of 1914 was the sinking of the "Aboukir," "Hogue" and "Cressy" with over 1,200 men on Sept. 22 by Weddigen in U9. Though the feat was an easy one, for the ships conveniently stopped to lower boats and waited to be torpedoed, its effect was to raise the submarine in the estimation of both belligerents from a difficult and dangerous toy to a formidable weapon. Imaginative lookouts saw submarines everywhere and after a credible report that periscopes had been

seen in Scapa Flow, the Grand Fleet withdrew from there on Oct. 16 till the Flow could be made secure by submarine-proof net-booms.

In actual fact, no U-boat had yet been near Scapa. It was in southern waters, in an attempt to hamper the transport of our troops to France, that the German effort had been directed. An attack on the Dover patrol on Sept. 27 decided the Admiralty to prevent entrance into the Straits of Dover by a minefield. This was laid early on Oct. 3, the public announcement of its limits being made to the press the evening before. Possibly the Germans regarded the minefield as existing only on paper; their submarines continued to enter the Channel by the Straits. U20 left on Oct. 10 to attack the large convoy of Canadian troops expected at Southampton. She was sighted and hunted by the Dover Patrol, and returned to Germany by the northabout route, being thus the first submarine to circumnavigate the British Isles. U17, returning from a cruise, stopped the British merchant ship "Glitra" off Stavanger and sank her. This was the first merchant ship to be sunk by a submarine.

Before the year ended Wegener in U27 sank a seaplane carrier off the Belgian coast and Forstmann in U12 penetrated into the Downs and torpedoed the guardship "Niger" in the middle of all the shipping congregated there. Of our own submarines E3 was torpedoed by Wegener off the Ems; the other E-boats had had little success though Horton succeeded in sinking a German destroyer on Oct. 6. A bold attempt was made by 5 U-boats to locate the Grand Fleet; one of them on Oct. 24 entered Scapa Flow, once more the Grand Fleet base, but at the time the battle fleet happened to be out exercising. One of these 5 U-boats, U18, was hunted by small craft till she crashed on to the Orkney rocks and sank. Once more the submarines returned without precise information of our capital ships, and the stream of transports passing to France became as before the chief objective. Schneider in U24 torpedoed a crowded steamer off Cape Gris Nez, assuming that the passengers were soldiers; but they were Belgian refugees, women and children, and the crime gave a shock to the civilised world. Hersing in U21 destroyed two vessels bound for Havre, though neither was carrying any goods consigned to military authorities. The leisurely nature of his proceedings in stopping the vessels gave plausibility to the current idea that a merchant ship with hidden guns would have a good chance of destroying a submarine; and on Nov. 26 the Admiralty gave orders for one to be so fitted, the railway steamer "Victoria," which left for her first trip three days later. She was the first of the long and honourable line of the so-called "Q" ships. Hersing's operations off Havre led to the institution of two measures which rendered the troops for France more safe; from that time on they were allowed to cross only at night in fast ships and these were always escorted by destroyers. On New Year's Day the old battleship "Formidable" was sunk by Schneider. This first campaign extended to the end of Jan. 1915. At the end of that month Hersing appeared off Barrow-in-Furness, fired a few shots at an airship shed after having been watched for half an hour by the battery commander, and then proceeded to Liverpool Bar where he sank by bombs three small steamers. Schwieger in U20 proceeded to the Channel with orders to sink without warning large vessels steering for French ports; he carried out these instructions so thoroughly that three ships approaching Havre disappeared, one, the "Oriole," with no survivor. Schwieger became later one of the most notorious exponents of ruthless submarining.

So far the campaign had been against normal objects of warfare—warships, transports, military works. But its results were insufficient to warrant the supposition that by submarines and minor weapons could Germany ever succeed in reducing the British Navy to an equality with her own. After considerable debate and hesitation she decided to use her submarines against a new objective.

### II. THE ATTACK ON COMMERCE

*Submarine Blockade Declared.*—Early in Jan. Admiral von Pohl, Chief of the German Naval Staff, proposed that submarines

should be used as the agents in a commerce blockade of the British Isles. At first the Kaiser refused to sanction the measure, but he consented after the fight on the Dogger Bank on Jan. 24 had demonstrated the danger of operations by large ships. On Feb. 2 appeared a note warning neutral shipping to avoid the Channel, where German submarines would attack vessels bound for France, regardless of the flag carried. This was followed on Feb. 4 by a wider statement that after Feb. 18 enemy vessels near the British Isles or in the English Channel would be destroyed, and that neutral ships ran grave risks of being treated in the same way, since British ships frequently wore neutral ensigns as a ruse. Scandinavian vessels were advised to go round the Shetlands.

*Anti-submarine Measures, Feb. 1915.*—Great Britain used the fortnight's respite in preparations to meet the attack. To destroy the German submarines in their own bases was realised as impossible without large armies, and these the military authorities preferred to use on other fields. Beyond the laying of mines in German waters, anti-submarine war was therefore limited to defensive measures. Fifty coasting vessels were provided each with a gun aft. There were already a number of trawlers armed and working as auxiliaries to the east coast destroyer patrol; this "auxiliary patrol" was now increased to over 500 vessels and distributed round the coast to operate from various bases. Trawlers and destroyers in many cases were already fitted to tow an explosive charge with which to attack a submerged submarine; but what was felt to be the most hopeful weapon was the "indicator" net, of 6-ft. mesh in large detachable sections each trailing a buoy which should flame at night. These nets were shot from drifters, each of which could manage a mile of them. Arrangements were made for indicator net lines to be maintained in various places, particularly in the North Channel between Ireland and Scotland, across the southern exit of the Irish Sea, and, most urgent of all, across the Straits of Dover. So important was this last that Rear-Admiral Hood, commanding at Dover, was instructed that the barring of the Straits was his principal duty.

*Campaign in Home Waters, 1915.*—To carry out the ambitious project of stopping the imports of Great Britain, Germany had only 18 submarines capable of long voyages, the highest numbered boat being U35. But over 160 of various types were building or on order. The first boat to proceed for the new campaign was U16 (Hansen), which left Germany on Feb. 9 for the Channel with orders that up to Feb. 15 only ships about to enter French ports were to be destroyed without warning; after that he should sink any vessel which might seem to be British, regardless of the ensign she wore. On the way to Dover Strait, Hansen gave chase to the steamer "Laertes" (Capt. W. H. Probert), who, though his vessel was unarmed, refused to surrender in spite of machine-gun fire, and eventually tired out his pursuer. In the Channel, Hansen torpedoed a British collier without warning, sank a French collier by bombs after surrender, and returning on the 19th torpedoed without showing himself the Norwegian tanker "Belridge," the first neutral to feel the sting of Germany's new campaign. His place on the transport route to France was to be taken by U6, but that boat was rammed off Beachy Head by the steamer "Thordis" (Capt. J. W. Bell), and had to return for repairs.

During the first week of the campaign, Feb. 18 to 25, U30 sank two vessels off Liverpool and U8 torpedoed without warning 5 off Beachy Head. Observing that such landmarks as these were places where shipping naturally converged the Admiralty now insisted that ships should avoid all prominent headlands and keep in mid-channel; and in the hope of rendering Dover impassable obtained on March 1 Treasury sanction for the building of a fixed boom of nets from Folkestone to Gris Nez. This proved a formidable and indeed hopeless undertaking; and throughout this campaign the destroyer patrols and the drifting nets were the only obstacles to the passage of submarines.

*The Base at Zeebrugge.*—U8 had come from Zeebrugge. As soon as the Germans captured the Belgian coast they established a Naval Corps there under an Admiral. He repeatedly

urged the favourable situation of Zeebrugge as a base for submarine operations in the Channel, but had to be content with occasional visits of U-boats, until the special types of small UB- and UC-boats should be ready. One objection was that Zeebrugge was specially liable to air attack; U14, ready to start for attack on the transports, was damaged by aeroplane bombs and on Feb. 14 returned to Germany for repairs.

Submarines continued to pass Dover Strait and sink vessels in the Channel and on the west coast. On March 4 the net and destroyer patrols succeeded in sinking U8, whose crew surrendered. The Admiralty refused to accept as lawful the German method of sinking ships without warning and detained these men for trial, a measure that produced such violent reprisals in Germany that they were eventually treated as ordinary prisoners of war. Weddigen in U29 after sinking 6 vessels, one a defensively armed ship, was himself rammed on March 14 by the battleship "Dreadnought" and drowned with all his crew. Four days earlier U12 was rammed by the destroyer "Ariel" and surrendered. A third loss at this time caused special uneasiness in Germany. U37, a new boat, operating in the Channel, disappeared without a trace. Other boats had reported nets, mines and various obstructions in the Straits; and it seemed too dangerous to allow the scanty force of U-boats to run unnecessary risks. On April 10, although the Army Command was pressing for more intensive attack on the transports of the B.E.F., High Sea Fleet submarines were ordered to make their passage to and from the Channel only by the north of Scotland. Thus the Dover net had proved effective; but by the irony of fate, it was on that very date that Admiral Hood hauled down his flag at Dover to be superseded by Admiral Bacon. Henceforward U-boats found it so difficult to approach the transports route that they ceased to enter deep into the Channel.

*The UB-boats.*—Attack in that area was left to the little UB-boats. The first 18 of this class built specially to work from Flanders, had a surface speed of only 6½ knots and had as their armament at first merely two torpedoes and a few rifles. Such vessels could manifestly operate only by torpedoing ships without revealing themselves. The first completed was UB10, but the first success fell to UB4 which on April 10 torpedoed the Belgian relief ship "Harpalyce." On the 14th the Dutch "Katwyk" was torpedoed without warning by one of these UB-boats near the North Hinder light vessel. Although nets were moored off the Belgian coast and the patrols were numerous and active, these feeble little UB boats fought the tide ripers and navigated amongst the sand banks of the east coast sinking ships and raiding the fishing fleets. On June 21, UB6 passed through the Dover barrage and reconnoitred Boulogne. Thenceforward the Dover patrol could not keep them out.

*The UC-boats.*—Flanders was also a base for submarine minelayers, known as the UC class, which instead of torpedo tubes carried mine tubes containing mines. The UC-boats, no faster than the UB's and totally unarmed, were intended only as secret minelayers. Their method was to creep at night to some light vessel or buoy and lay their mines close to it. The first to reach Flanders was UC11 which on May 29 started for her maiden cruise to mine the South Goodwin. She fouled an indicator net and was chased till she unknowingly entered a British minefield. Escaping the double peril of net and mine she proceeded to her objective, and laid her field. On her second trip she was caught in another net, from which, however, she disentangled herself without provoking a hunt. The mines laid by the UC-boats being always on the thickly frequented East and South coast routes claimed many victims, regardless of nationality. An account of the Admiralty's method of dealing with the UC mines belongs more to Mine-sweeping (*q.v.*).

*Attack in the Western Approaches.*—After April 10 U-boats operated only in the North Sea and in the Western Approaches. In the North Sea the attack was chiefly on shipping of the Scandinavian Powers, especially early in May when three of the latest submarines sank between them half a dozen Danish, Norwegian and Swedish steamers, besides fishing vessels. Germany's plan was to keep three U-boats at work in the Western Approaches,

a scheme which employed 9 boats, 3 working, 3 on passage, 3 resting. Only the best boats could reach Southern Ireland, where they found easy prey in the open waters between Ireland and Ushant. It was no part of the German intention to exempt passenger vessels from attack; in their announcement of Feb. 4 such had been specifically mentioned as liable to danger, and several large liners were sunk. The liner "Falaba" was torpedoed, after five minutes warning, by U28, 57 passengers being drowned; and on May 7 Schwieger in U20 torpedoed the "Lusitania" without any warning and drowned 1,198 men, women and children.

The chorus of praise which in Germany greeted this masterpiece of the submarine war had soon to be modulated into a minor key, for among the murdered were citizens of the United States, whose President now protested against Germany's methods. Two American steamers, the "Gulflight" and "Nebraskan" were torpedoed without warning in May; but as they both reached port, the irritation roused in the United States by their cases was swamped by the rising tide of anger over the "Lusitania." So powerful was the feeling that the German political authorities gave way, and on June 5 issued orders that large passenger ships were to be spared unless they made deliberate attempts to injure submarines, a reservation that was to have important consequences. On Aug. 19 Schneider met the White Star liner "Arabic" and assuming that she intended to ram him torpedoed her without warning with the loss of 44 lives. American indignation flamed up anew. To placate it orders went out on Aug. 30 that no liners were to be sunk without due regard to the safety of passengers.

This was followed on Sept. 20 by the total suspension of submarine warfare on the west coast and in the Channel, in effect, the conclusion of the first submarine campaign in Home Waters. In the course of its progress the decoy ship idea had been developed in three forms—a small tramp steamer with concealed armament, a trawler apparently fishing but really towing a submarine and a sailing smack with a hidden gun. None of these types of vessel was worth a torpedo, and the hope was that the enemy would come close either to fire guns or to send a party on board with bombs. The first success fell to the "Prince Charles" (Lt. Mark-Wardlaw), outwardly a slovenly collier, which on July 24 destroyed U36 west of the Orkneys. On the day the "Arabic" was torpedoed, another decoy ship, the "Baralong," sank U27; a month later she sank U41. By the towed submarine decoy U40 was torpedoed on June 23 and U23 on July 20. The armed sailing smack "Inverlyon" (Gunner E. M. Jehan, R.N.) sank UB4 on Aug. 15.

The first submarine campaign against merchant ships resulted in the loss of 166 British steamers and 168 British fishing vessels, the latter a class which by the Hague Convention should have been spared. France, Russia and Belgium had lost 34 ships between them. But the attack was not only on belligerents; it was directed against all the nations of the world. Of the neutrals, Norway, having the largest mercantile marine, had suffered most; 51 Norwegian ships had been sunk by submarines alone. Sweden and Denmark each lost 15, Holland and Spain 2 each. Several of these neutral vessels were torpedoed by UB-boats at night without warning. These losses are exclusive of ships which struck mines; Holland had suffered specially by these.

*Spring Campaign of 1916.*—During the winter the naval authorities in Germany managed to wring from the political heads permission to torpedo defensively armed vessels without warning, though passenger ships were still to be spared; and in Feb. 1916 the attack began again, many more submarines both of the U and UB classes being now ready. As before, the Southwest approach was its main theatre. In the former campaign U-boats had quickly taken advantage of the Admiralty's orders that ships were to keep away from land and thus incidentally away from protection, since the auxiliary patrol was not then effective more than 40 m. from shore. But now, a new principle was adopted. As soon as a submarine was known to be present in a certain area, all outbound shipping which would pass that area was held in port until it was thought the enemy had gone away, and incoming

vessels were directed by wireless to hug the shore where the patrols were thickest. In the southern part of the North Sea the UB-boats secured some neutral victims, notably the large Dutch liner "Tubantia," torpedoed without warning on March 16. They also torpedoed at night several vessels at anchor off British and French ports. Particularly was this the case with Havre, where store ships had frequently to wait for hours before they could be admitted to the congested harbour. As a deterrent to submarine action there the Admiralty sent over a detachment of drifters, whose nets, now studded with mines, succeeded in accounting for UB26 on April 5. A fortnight earlier the Q-ship "Farnborough" (Comm. Gordon Campbell) destroyed U68, off the southwest corner of Ireland.

On March 24 Pustkuchen in UB29 torpedoed the French packet "Sussex," crowded with passengers for Dieppe. After the "Lusitania" correspondence, Germany had promised President Wilson not to molest passenger ships of any nationality and not to torpedo without warning any unarmed vessel. The promise had been disregarded from the beginning; indeed, the first vessel attacked in this second campaign, the "Arbonne," had been torpedoed without warning and without survivor by UB2 on Feb. 21; but the President first took notice of the "Sussex" incident. Thoroughly roused, he sent what was practically an ultimatum demanding the immediate abandonment of Germany's "present methods of submarine warfare against passenger and freight-carrying vessels." The German Govt. surrendered and at the end of April stopped this second campaign.

Between the beginning of Feb. and the end of this spring campaign submarines destroyed 58 British mercantile and fishing vessels and 18 Norwegians; France lost 3 steamers, and several other nations one or two apiece.

*Autumn Campaign of 1916.*—Throughout the summer of 1916 the U-boats with Adml. Scheer were employed with the fleet, and merchant ships in Home Waters were left alone. In July, however, the Flanders submarines made a serious raid on North Sea fishing vessels, sinking 47 between July 4 and Aug. 6, among them the little "Mary Ann" of 5 tons, the smallest vessel sunk by a submarine. The UB-boats sank a few other vessels, including the "Calypso," torpedoed without warning on July 10, with a loss of 30 lives. In Sept. began a continuous attack on the vessels carrying munitions to Russia; between Sept. 20 and Oct. 16 a total of 13 Norwegian, 4 Russian and 3 British ships were sunk in the Arctic Ocean. In response, four Q-ships and 3 British submarines were sent to operate on the Murman coast but achieved no success, though two German submarines were destroyed by Russian patrols.

In the summer of 1916 the political situation of the Allies was, perhaps, at its lowest ebb throughout the War. Germany's prompt surrender to President Wilson's ultimatum at the end of April diminished the tension across the Atlantic, whereas the Allied blockade was now so effective that it drew from the United States a strong protest. Encouraged, doubtless, by this reversal of the situation Germany decided to renew submarine warfare on commerce, theoretically in accordance with prize law. The attack was at first mainly against Scandinavian shipping by which iron ore amongst other things was brought across the North Sea and coal carried to France and Italy. In Sept. and Oct. Norway lost 5% of her mercantile marine. In the English Channel the UB-boats, now armed with guns of some size, and in the western approaches the large U-boats, did much damage; as a rule they took care to give some warning except in the case of defensively armed vessels, though the destruction of 3 vessels without warning at the end of Oct. caused the drowning of 85 non-combatant seamen. The rate of sinking increased so much that Adml. Jellicoe took the unusual step of writing direct to the Prime Minister drawing his attention to the fact that the loss of shipping alone might soon cause the Allies to conclude peace. As a result of the conference which followed he was appointed First Sea Lord to carry into effect the various proposals he made for dealing with submarines. By that time the tension between the United States and Germany had been increased by the appearance

of U53, Lt.-Comm. Rose, off Nantucket on Oct. 7. There within sight of land Lt.-Comm. Rose sank 5 ships, 3 British, 1 Dutch and 1 Norwegian. His voyage out and back occupied 42 days. No other commerce-destroying submarine visited America in 1916; perhaps the emotions stirred by Rose were not quite what was intended.

In face of the severe attack on their ships, Norwegian owners were inclined to keep the remainder in port; and since British munition works and the continuance of the War by France depended on the cargoes they carried, the position was serious. Attempts were made to maintain a patrolled lane across the North Sea, but between Sept. 1916 and Jan. 1917 inclusive, 170 Norwegian, 29 Swedish and 50 Danish ships were destroyed by German submarines, as against 86 British sunk in Home Waters in the same period.

One of the problems to be solved was to find some efficient method of damaging a submarine when it was submerged. The explosive charge towed by a patrol vessel soon proved to be nearly useless, since it could easily be avoided; and experiments were made with bombs which could be dropped or thrown overboard. By the middle of 1916 had been evolved the "depth charge," a large bomb which exploded at either 40 or 80 ft. below the surface, according as set. Depth charges were heavy things and had to be heaved over on to the submarine; they could, therefore, be used only at very close quarters. Much was hoped from them; but it was soon apparent that unless the bomb exploded within 30 ft. or so of the submarine, it did not damage it sufficiently to bring the boat to the surface either on account of the dislocation of its machinery or to allow the crew to escape. It was not till the following year that the depth charge, fired from a sort of howitzer, became a really formidable weapon in the hands of the anti-submarine forces, which in the autumn campaign had mainly to rely on the ram, the towed charge, the net, the mine and the gun. These effected the destruction of only three or four U-boats between Sept. 1915 and Jan. 1917.

At the end of Nov. 1916 a success fell to the Q-ship "Penshurst" under Comm. F. H. Grenfell, R.N., which gives an excellent illustration of the work of a decoy ship. The "Penshurst" had been cruising for a year and never met a submarine till Nov. 29 1916, when she was fired on by one near the Lizard. The circumstances of light and range were unfavourable to the "Penshurst" and she had to reveal her armament without making sure of her quarry, which submerged and escaped. Realising that the character of his ship was now revealed, and that no submarine would approach him on the surface, Grenfell returned to harbour. In the course of the night he had his ship painted in a different way and altered the appearance of her masts, so that when the "Penshurst" sailed next morning the submarine commander would never suspect her of being the vessel which had opened fire on him from hidden guns. Before long, the "Penshurst" took in a wireless signal reporting a submarine had been sighted near Guernsey.

Grenfell steered in that direction and soon sighted the enemy. But just then a seaplane flew over and dropped a bomb near the submarine, making it submerge. The "Penshurst" carried depth charges as well as guns and Grenfell was about to make arrangements for dropping these when the submarine came to the surface and began to shell the "Penshurst." This was Grenfell's opportunity. He stopped his ship; sent away in boats all his crew but the gunners; and when the submarine approached to finish off the apparently abandoned "Penshurst" he sank her instead with his concealed guns. Thus UB19 met her end. Six weeks later, Grenfell in the "Penshurst" destroyed UB37, after having silently endured a gunfire which killed some of his gun's crew and wrecked his depth-charge dropping gear.

*The Mediterranean to Jan. 1917.*—In the Mediterranean, as in the North Sea, submarine operations were at first limited to military objectives, though they soon degenerated into commerce warfare. Austria had a dozen or more submarines which she used against warships, the first to suffer being the French "Léon Gambetta," flagship of the Adriatic patrol, sunk on April 27 1915, with the loss of 570 lives. In June the British light

cruiser "Dublin" was torpedoed but did not sink. When Italy joined the Allies on May 23 the Italian Navy supplied targets for Austrian submarines and before the end of July two Italian surface men-of-war and an Italian submarine had been sunk by the Austrian U-boats. The result was that the heavy ships of the Italian Navy became almost entirely retained in port.

A more important object for submarine attack was provided by the British and French squadrons operating in 1915 for the capture of the Gallipoli peninsula. At the end of April one of the most efficient German submarine commanders, Hersing in U21, left Germany for Constantinople, a journey of unprecedented length. Arrangements were made to supply him with oil half-way; but when he met his supply steamer he found that she had brought the wrong kind of oil and he decided to go on without it. He gave up the idea of making Constantinople and proceeded instead to Cattaro in the Adriatic, reaching it on May 13 with only half a ton of oil left. A week later he received orders to attack the ships bombarding at the Dardanelles. Before the end of May 1915 he sank the battleships "Triumph" and "Majestic" and entered Constantinople, having dealt the distrusted Dardanelles enterprise a wound from which it never recovered. Germany also sent by train UB- and UC-boats in sections to be erected at Pola; by the autumn U33, U34, U35, U38 and U39, the latest and best U-boats, had arrived at Cattaro, bringing up the German submarine force in the Mediterranean to 5 large U-boats, 4 UB-boats and 4 UC-boats. Three of the last class worked from Constantinople, the remainder from the Adriatic against merchant vessels. In Nov. Arnauld de la Perrière was appointed to U35 and, in spite of his French name, proved himself one of the most redoubtable German champions in the war against merchant vessels.

In the Mediterranean the conditions were greatly in favour of the U-boat; the clear air and smooth seas gave the man at the periscope a better chance than his colleague in home waters, peering through the mists and storms of the North Sea and Atlantic; moreover, the immense distance between Gibraltar and Malta, and between Malta and Suez, precluded the possibility of efficient patrol at any but a few points. All the submarine commander had to do was to go out on to the steamer track and pick off the ships one by one as they came up to him. If they were armed he could torpedo them without revealing himself; if unarmed they could be shelled into surrender. The only dangers he could not avoid were the very rare meetings with Q-ships and the passage of the net barrage maintained after Sept. 1915 by British drifters across the Otranto Straits in the hope of stopping approach to the submarine bases in Austrian waters. The protest of President Wilson had no effect in the Mediterranean and the sinking of merchant vessels continued without those interruptions which cut the Home Waters campaign into such well-defined sections. When the President was promised that submarines would operate in accordance with their own prize law a month or two elapsed before there was any resumption in the Mediterranean of the practice of torpedoing at sight. But in Nov. 1915 the "Californian," "Treneglos," "Orange Prince" and "Hallamshire"; in Dec. 1915 the "Persia" and "Clan MacFarlane"; and in Jan. 1916 the "Glengyle" were all torpedoed without warning. All were large ships, the "Persia" being a P. & O. liner full of passengers; the loss of life in her case was 334.

For a few months in the autumn of 1915, when it seemed possible that the Turks would attack Egypt, the German submarines were employed in conveying war material to the restless tribes to the westward of the Egyptian border. On one of these trips U35 sank the patrolling British armed merchant cruiser "Tara," whose crew were driven by Senussi into the interior, where they subsisted on snails and such meagre provisions as their captors consented to dole out until they were rescued by the Duke of Westminster's armoured cars. After the evacuation of Gallipoli peninsula, the German submarines confined themselves to attack on merchant ships. In the 18 months from Hersing's arrival to the end of Jan. 1917, a total of 200 British, 180 Italian and 52 French ships were destroyed in the Mediterranean.

During this period seven Austrian submarines had been destroyed, three by Italian men-of-war, one caught in the Otranto barrage, three others by unknown circumstances. Several of the German UB- and UC-boats were lost from various causes; but none were destroyed by British or Allied warships. The Q-ship "Margit" had a chance of opening fire on a submarine in Jan. 1916, but did not succeed in sinking it. On the whole, the Mediterranean was a safer field of operation for submarines than home waters.

*Operations of British Submarines in the Baltic.*—British submarines had no such easy work as the German U-boats. Germany sent no troops abroad, and her imports reached her from contiguous countries by land or in short passages across the Baltic. In that sea several British submarines operated. The first was E1 (Lt.-Comm. N. F. Lawrence) which passed through the Sound into the Baltic on Oct. 17 1914. She fired two torpedoes at, but missed, a German cruiser near the entrance to Kiel Bay and seriously disturbed what had been thought the security of that sea. E9 (Lt.-Comm. Max Horton) arrived in the Baltic two days later. After a few days in harbour the two E-boats commenced operations against the German fleet and though they did not succeed in sinking any ships, the knowledge of their presence brought to an end the safety with which German forces had exercised in the Western Baltic. The ice of the Baltic winter soon kept the British submarines in harbour to wait for the spring. In May Max Horton torpedoed a German cruiser; in June, a destroyer and collier and in July an old cruiser.

The Germans by then were making a strenuous effort to capture Riga. To assist in the defence the Admiralty despatched E8 and E13 in August. The latter, through a breakdown of her compass ran ashore in Danish territory on Aug. 19, and was allowed by the Danes 24 hours to endeavour to refloat. Before this interval elapsed two German destroyers appeared and opened fire on her and on the seamen swimming from her towards the Danish shore, causing the death of 15 of them. This outrage on humanity and Danish sovereignty was possibly the outcome of German irritation at the interference with their plans due to the activity of our submarines; on that same day E1 torpedoed the battle-cruiser "Moltke" off the Gulf of Riga and sent her back to port for repairs. Two days later the Germans abandoned their attack on Riga. In the autumn our submarines were used chiefly in stopping the passage of iron ore from Sweden to Germany. Between Oct. 11 and 23 they sank 14 large German steamers loaded with ore and so effective were their operations that 37 other steamers ready to sail were held up in Swedish ports till a system of convey could be organised. In Nov. the old cruiser "Prinz Adalbert" was sunk by E8 and in Dec. a light cruiser and a torpedo-boat were destroyed. During that autumn and winter some 20 German steamers aggregating 45,000 tons were sunk or seriously damaged by our submarines, producing a sort of paralysis in the transport of iron ore to Germany.

By July 1916 there were 8 British submarines in the Baltic, 4 of the E class and 4 of the C class; Commander Cromie of E19 took command of this Baltic flotilla, which was put under the direct orders of the Russian Commander-in-Chief. Throughout 1916 and 1917 the boats were used by him in an interminable series of reconnaissances; they had no opportunity of interfering with the iron-ore traffic and little chance of attacking warships, since the essence of reconnaissance is that the presence of the watcher should be unsuspected. The outbreak of the revolution in Russia still further limited their activities. In Nov. 1917 C32 was so badly damaged in an encounter with German patrols that it was decided to destroy her and send the crew home. Finally, on April 3 1918, news having been received that the Germans were advancing on the submarine base at Helsingfors, the whole flotilla went out to sea through the ice and was blown up by its officers. Thus perished E1, 8, 9 and 19 and C26, 27 and 35. Comm. Cromie never returned to England; he was killed by Bolsheviks on the steps of the British Embassy.

*British Submarines at the Dardanelles.*—The operations at the Dardanelles gave opportunities for some remarkable exploits by the British submarines attached to the Eastern Mediterranean

Squadron. Their ability to interfere with Turkish transport to the Gallipoli peninsula was fully realised; but the passage of the Dardanelles at first seemed impracticable. The Straits are 27 m. long and for  $3\frac{1}{2}$  of these miles they are only 1 m. wide; there, in the Narrows, it was known that anti-submarine nets, booms and minefields had been placed; but the nets and booms, it was thought, might be passed by specially fitted submarines. Lt. N. D. Holbrook, in B11, was the first to try. He successfully negotiated the passage of the minefields and on Dec. 11 1914 torpedoed a Turkish cruiser, the "Messudieh." On the return journey his compass became unserviceable, and to the already great enough hazards of the mines and the pursuit was added the difficulty of navigating an unfamiliar channel without a compass. Surviving all these perils he returned and was awarded the Victoria Cross. No further attempt was made till the spring of 1915. In April, E15 (Lt.-Comm. T. S. Brodie) opened the campaign, but unfortunately grounded some 10 m. up the Straits and was lost. Strenuous efforts were made by other submarines, destroyers and even battleships to destroy the hull of E15 so that the Turks could not use her; but the activity of the defence foiled them all. It was left to one of a pair of picket boats which crept up the Straits on a pitch black night to find and torpedo the wreck of E15.

The ill-luck of Lt.-Comm. Brodie did not deter his colleagues, British and French, from following. E14 (Lt.-Comm. E. C. Boyle) sank three Turkish ships, including a transport with 6,000 troops aboard; but AE2, a submarine of the Australian Navy, was sunk by gunfire on April 30. In May the French submarine "Joule" struck a mine and was lost in her first attempt at the passage. E11 (Lt.-Comm. M. E. Nasmith) returning from a successful voyage found a mine sitting on his bows, but was able to get rid of it by clever manoeuvring. He had penetrated as far as Constantinople itself, where he torpedoed and sank a Turkish gunboat. Near Rodosto he sank several transports and store ships, his nearness to shore in one case being such that he was forced to retire by a party of horsemen. He returned to Constantinople and torpedoed the man-of-war "Stambul," in the Golden Horn itself. It was the first time that an enemy had appeared in that harbour since it had become Turkish; and his exploit had the effect of stopping for the time all sea communication between Constantinople and Gallipoli.

E12 (Lt.-Comm. K. M. Bruce), E7 (Lt.-Comm. A. D. Cochrane), E2 (Comm. David Stocks), E20 (Lt.-Comm. C. H. Warren) and H1 (Lt. Wilfred Pirie) also made the difficult and dangerous passage with more or less striking results. E12 on one occasion encountered and sank a decoy which carried a masked gun. Amongst other exploits Lt.-Comm. Cochrane attacked the railway line and blocked it for a time. E14 and E11 were up the Straits together at the end of July and sank between them some 30 ships bound for Gallipoli. Every possible obstacle was put in their way by the Turks, who had erected a powerful barrage at Nagara. The French submarine "Mariotte" fouled a mine, and while trying to free herself was shelled into surrender (July 26). Bruce in E12 cruised in the Sea of Marmora from Sept. 16 to Oct. 25, 40 days, during which he sank 34 ships and did much damage to magazines and railways ashore. On the way back the bows of his boat carried away part of the Nagara obstruction and E12 was dragged down to a depth of 245 ft. before she could gain control. The entanglement, whatever it was, was scraped off her by a chain boom a little lower down the Straits and though she broke surface in her plungings and came under fire from guns and torpedoes, she managed to reach Helles in safety.

In Nov. E11 and E20 and the French submarine "Turquoise" went up the Dardanelles to continue the disturbance to Turkish communications. Only one of them returned. The "Turquoise" ran aground and was captured intact. A paper found by the Turks in her revealed a rendezvous, and by despatching a submarine to that spot they were able to torpedo E20. Nasmith in E11 cruised for 47 days in Turkish waters; before returning he destroyed or rendered useless 11 steamers and 35 sailing vessels, in face of all the barrages, patrols and batteries set up to prevent him and in spite of the fact that shipping for safety's sake had

been kept in harbour as much as possible. When the Gallipoli peninsula was abandoned at the end of 1915 the necessity for running the risk of penetrating the Dardanelles no longer existed and the operations of British submarines came to an end; but the record of their work will always remain an inspiring chapter in the history of the British Navy.

*Analysis of the Autumn Campaign.*—During the autumn campaign of 1916, German submarines in Home Waters had been acting under some sort of restrictions as regards sparing passenger ships and refraining from torpedoing vessels without warning. These restrictions were not in accordance with Admiral Scheer's ideas; his view was that the submarine as a weapon could best achieve results by surprise; and to him it seemed unreasonable to expect submarine commanders to expose themselves to the great risks known to exist if they came to the surface and warned vessels before sinking them. Most large merchant ships were now armed for defence, and some had even sunk attacking submarines; and, moreover, there was always the possibility that a tramp steamer, harmless to the outward eye, might really be a Q-ship, to attack which was death. Only reluctantly had Scheer allowed his High Sea Fleet submarines to participate in the autumn campaign, and he expected little good from it. The results exceeded anticipation; indeed, Oct. 1916 proved the worst month of the three campaigns of 1915 and 1916. In that month submarines destroyed 148,000 gross tons of British shipping and 124 foreign ships of 164,000 tons—a total of over 300,000 tons for all the nations of the world. The progress of the campaign in Dec. 1916 and Jan. 1917 can be seen in the following table:—

*Destroyed by Submarines*

|                | Dec. 1916 |            | Jan. 1917 |            |
|----------------|-----------|------------|-----------|------------|
|                | Ships     | Gross tons | Ships     | Gross tons |
| British        | 39        | 110,160    | 51        | 111,974    |
| Allies         | 58        | 66,690     | 63        | 58,253     |
| Norwegian      | 32        | 43,537     | 34        | 55,487     |
| Danish         | 17        | 16,113     | 13        | 17,151     |
| Other Neutrals | 21        | 39,900     | 19        | 42,142     |
| Totals         | 167       | 276,400    | 180       | 285,007    |

An interesting feature in the campaign is that the shipping of the neutral nations suffered more severely than British; in Dec. 70 neutral ships to 39 British and in Jan. 66 neutral to 51 British, of which 16 were small fishing craft. Norway, in particular, lost nearly as many vessels as England. Such favourable results of the submarine attack on merchant vessels, restricted as it was, strengthened the arguments of that party in Germany who were convinced that, if all restrictions were removed, submarines could double their rate of destruction and would, in any case, bring to a standstill the Norwegian traffic to England. Their arguments gained the day and it was decided to carry on the submarine attack as in 1915 without restrictions. The step would probably compel the United States to break off relations; but the submarine party were confident that before America's military forces could affect the issue of the War, it would be over, with England vanquished. So certain did this seem that Germany put forward a proposal of peace, but as it was couched in terms such as a victor uses to the vanquished, it was rejected.

Then, on Feb. 1 1917, was re-introduced the original method of unrestricted warfare. Areas enclosing the British Isles and France, the Mediterranean and, later, the Portuguese Atlantic Islands and the area round Archangel, were declared war zones; vessels of any nationality or character found in the war zones would be destroyed, and though no special efforts would be made to kill the crews, consideration for the safety of their lives would not be allowed to hinder the submarines in their work.

### III. THE FINAL STRUGGLE

*Second "Unrestricted" Campaign, Feb. 1917 to Nov. 1918.*—To carry on the unrestricted campaign Germany had 111 sea-going submarines of the U, UB and UC classes. Though the UC-boats were still primarily minelayers whose operations are treated elsewhere (see MINELAYING), they now carried guns and

a few torpedoes and could therefore wage war on merchant vessels in the same way as the other classes of boats. Attached to the High Sea Fleet there were 29 submarines active and 20 under repair, the figures for the other stations being: Flanders 31 and 2; Baltic 0 and 2; Adriatic 7 and 17; Constantinople 2 and 1; a total of 69 at work and 42 under repair.

The declaration of unrestricted warfare, which meant that neutral vessels would again be sunk without warning, had a serious effect on the departure of ships from Scandinavian countries. This had been foreseen by the British Admiralty and was countered by the detention of each Scandinavian ship already in British ports until it was known that a corresponding vessel had sailed for England. Even with the reduction of traffic at sea resulting from the natural reluctance of non-belligerents to take the risk of entering the war zones the losses were:—

|         | February |            | March |            | April |            |
|---------|----------|------------|-------|------------|-------|------------|
|         | Ships    | Gross tons | Ships | Gross tons | Ships | Gross tons |
| British | 114      | 260,000    | 146   | 287,000    | 196   | 522,000    |
| Allies  | 77       | 77,000     | 114   | 115,000    | 108   | 145,000    |
| Neutral | 60       | 132,000    | 78    | 122,000    | 126   | 185,000    |
|         | 260      | 469,000    | 338   | 524,000    | 430   | 852,000    |

The rate of increase in losses was such that it seemed that the submarines would win the War for Germany. They were being completed faster than they were being destroyed so that their number increased from 111 on Feb. 10 to 127 on April 10. It was clear that the existing methods of fighting them were insufficient. Though all the forms of defence—detaining ships in harbour when a submarine was known to be about, causing ships to hug the shore, sending Q-ships on the traffic routes, arming more and more merchant ships, patrolling the avenues of approach—and all the weapons of attack, such as depth charges and hydrophones, were made more and more efficient they could not stay the tide of devastation. On April 19, the worst day for England of that worst month, 11 British merchantmen and 8 fishing vessels were sunk by submarines; and it has been stated that one out of every four vessels that left Great Britain in that month never returned. There were few successes during these first three months of the unrestricted campaign to hearten the defence; 2 UB-boats from Zeebrugge stranded on the Dutch coast, one UC-boat was blown up by mines off Sunderland, two British submarines torpedoed German boats, a destroyer "depth-charged" UC39, and Captain Gordon Campbell in the Q-ship "Farnborough" got U85 after an action which so nearly meant the loss of his ship and her gallant crew that he sent by wireless to Admiral Bayly at Queenstown the famous signal "Q5 slowly sinking respectfully wishes you Good-bye." It is satisfactory to know that she did not sink and that Captain Gordon Campbell survived to be the hero of a service manned by heroes. One episode of these terrible three months remained unique; the British submarine E50, proceeding under water, rammed a German boat also submerged, bringing into the realm of fact one of Jules Verne's most lurid fancies. Though she struck the German craft three separate blows, it escaped to tell the tale of one more peril for the U-boat.

*Escorted Convoys.*—Nevertheless, the submarine was winning. Unless some new and effective device could be put into action the surrender of the Allies was in sight. But the device was on the point of adoption. Scandinavian vessels refused to sail without escort and since it was impossible to escort each singly, they were gathered into convoys guarded by such armed vessels as could be spared. The principle of escorting a convoy had been in force for some months with the trade between Holland and England, and with the continuous export of coal to France, which being carried in slow vessels could be accompanied by armed trawlers; but the difficulties in escorting an ocean convoy had been considered too great for the means at our disposal. When at last the method was tried, these difficulties were found to have been over-estimated, and gradually the gathering of merchant vessels into escorted convoys became general. Special schools were established to train the masters of ships in the complicated

manoeuvres of zigzagging in squadrons and a large organisation came into being to collect each convoy and its escort. Between March and Aug. 8,000 colliers crossed the Channel to France in groups under some sort of escort and only 14 of them were lost.

In proportion as the convoy system became universal so did losses diminish. In May submarines sank 303 vessels of all nationalities totalling 550,000 tons; by Nov. the totals had fallen to 116 and 259,000 tons. Of 6,000 vessels convoyed between Norway and the Humber the loss by submarine action was 1%. One reason for this marked diminution was that now the U-boat had to run into danger to secure any prey. Before the introduction of convoy the submarine, by eluding the patrols, could deal with ships at leisure; but now she could not approach the bait without running the chance of being hooked. An ingenious system of dazzle painting was introduced and a convoy appeared in a periscope as a shapeless mass of stripes and blurs continually altering as the ships zigzagged; the escorting destroyers and trawlers forced a watching submarine to keep its distance, and its best chance was to catch a straggler. But this again was not infrequently a Q-ship, masquerading as a lame duck to invite attack. As the losses in shipping diminished the rate of destruction of submarines increased; in April, May and June of 1917 12 boats; in the next three months 20; and in the last quarter of 1917, 24 boats. To Comm. Maurice Blackwood in the Q-ship "Stonecrop" fell a special prize in Sept. when by admirable coolness and cunning he entrapped and sank U88. The "Stonecrop" was sunk next day by another submarine; but in U88, which disappeared with all hands, was the notorious *Schwieger*, who two years before had sunk the "Lusitania" and forced the United States to consider the possibility of joining the Allies. The United States declared war in April 1917 and before the end of the year had sent 37 destroyers to assist in convoy work. One of these destroyers, the "Fanning" while on convoy duty in Nov. 1917 dropped a depth charge on U58 and forced her to surrender. This was the only submarine known to have been destroyed by the United States forces.

Even with the addition of the United States destroyers it was not possible to escort every vessel, and on some routes merchant ships had still to fight for themselves. A curious fate overtook U28 in September. She met a vessel making for Archangel with ammunition; she first torpedoed it and then came close to sink it by gunfire. Her second shot burst among the ammunition, and the terrific explosion which resulted wrecked the submarine. U28 disappeared forever, leaving her men struggling in the water. Another Archangel steamer, armed for defence, fought a duel with a submarine till dusk without a decision. The submarine followed, intending to torpedo the ship in the darkness. She crept up on the quarter and fired two torpedoes; but the wary skipper, hearing an unusual noise, put his helm hard over and saw the white track of the torpedoes pass along his ship's side. Half an hour later he observed a luminous patch ahead of him and steering for it had the satisfaction of ramming his pursuer and ending her career. The submarine was U49; the steamer, the "British Transport."

Every type of vessel contributed to swell the number of lost submarines. In April 1918, Motor Launch No. 413, a vessel of a type built specially to deal with submarines, was on patrol in the Western Mediterranean, with her hydrophone out listening for the sound of a submarine's propeller. One was heard; and in the dim light of dawn, it could be seen rapidly approaching till it passed across the bows of ML413. Seeing the motor launch it submerged, but ML413 followed the wake and continuing along it and in the same direction till she was 150 ft. ahead of it she dropped four depth charges. The humming of the submarine's propeller instantly ceased. At daylight pieces of wood were seen floating, one a large fragment of varnished mahogany with steel hinges, undoubtedly part of a door from the interior of the submarine. The depth charges had been well aimed; they had torn the submarine to pieces. Later it was proved that this was UB71.

*The Attack Defeated.*—As 1917 progressed it became increasingly clear that the submarine attack on merchant vessels had

been countered. The number of submarines in commission reached its maximum of 140 in Oct. and then slowly diminished. They failed to impede either the transport of British troops to France or of American troops to Europe. Only one transport of the latter, the "Tuscania," was torpedoed, and in her case the loss of life was 44. Although four of the best U-boats were sent across the Atlantic specially to attack troop transports, and they destroyed 60 ships between them, not one contained troops. Moreover, one of the submarines, U156, was lost in the great minefield laid across the North Sea.

Throughout the War the British had made efforts to mine the exits from submarine bases and the entrance to the English Channel. They were ineffectual, owing mainly to the defects of the British mine. The advent of America into the War gave us access to her factories; and a newly designed mine, produced in immense quantities, made it possible to close Heligoland Bight from time to time and to make the Straits of Dover absolutely impassable. A similar barrage was established across Otranto Straits; and sinkings in the Mediterranean, where they had been specially heavy, began to diminish.

By the end of the summer of 1918 it was obvious to the German authorities that the submarine campaign could not be a success; and when the land operations also failed, the Flanders bases were evacuated, and the submarines there were blown up—all except one, UB116, whose commander, Lieutenant Emsmann, made one last effort. He reached the entrance to Scapa Flow on Oct. 28, but the search-light picked him up and his boat was sunk in the very gates of his enemies. The Armistice terms included the surrender of all German submarines. One hundred and thirty-eight still remained and these came in to Harwich. One hundred and ninety-two had been destroyed and seven interned. In addition, 7 Austrian submarines had been destroyed. An analysis of the methods of attack shows that the destroyers and patrol vessels with their guns, depth charges and rams accounted for 64 boats; mines and mine nets destroyed 43; British submarines torpedoed 18; Q-ships sank 11. The cause of loss of 19 is unknown; the remainder met their end from various weapons.

In view of certain controversies, it is of interest to record that no "Dreadnought" was sunk by a submarine, while U29 was rammed and sunk by H.M.S. "Dreadnought" herself. Of the submarine commanders, Arnauld de la Perrière is credited in Germany with having destroyed 400,000 tons of shipping in 10 voyages; Forstmann in U39 with 380,000 in 16 voyages; and Max Valentiner with 300,000 in 17 voyages. These were all in the Mediterranean where conditions were specially favourable. A more dangerous career was that of Steinbrink who in 24 voyages is claimed to have sunk 210,000 tons. He was operating from Flanders in UB- and UC-boats and had to overcome every obstacle that ingenuity could devise and, moreover, had to navigate among the tide-rips and shoals of the Channel and the east coast of England in boats of feeble engine power. Perhaps the most indefensible outrage perpetrated by the submarine commanders was the torpedoing by Patrig in U86 of the hospital ship "Llandovery Castle" on June 27 1918. The vessel was unmistakably a hospital ship marked with all the signs which should secure international immunity; she was 116 m. from land; but he sank her, and drowned 14 nurses and 226 other persons, only one boatload being saved.

*Conclusion.*—How near did the submarine campaign approach its object of reducing seagoing tonnage below the irreducible limit necessary for the needs of the Allies? One cause of the ferocity with which it was waged was the hope of terrorising merchant seamen into refusal to sail. This hope was from the first vain. The experiences of seamen whose ships had been sunk, instead of frightening them, stirred up rather their fighting spirit. When Admiral Jellicoe visited the Crystal Palace in 1918 he found there a number of merchant seamen at gun drill. Most of them had had their ships torpedoed under them. One, a steward, had suffered thus four times; he was learning to shoot so that he might sink a submarine with his own hand. As regards the destruction of tonnage trading with the Allies, so long as it exceeded by as much as 600,000 tons a month all replacement by

building, the campaign would most probably have brought the War to a close with Germany as victor. The figure of 600,000 tons net loss was perhaps exceeded in some of the months of the first half of 1917; thenceforward it fell, till in the summer of 1918 the rate of output of new shipping far exceeded the rate of destruction. The submarine campaign against merchant shipping was a bold experiment carried out, after some hesitations, with ruthless thoroughness. It failed. It strewn around the British Isles a rampart of broken hulls and the bones of gallant men. Its record is mostly the sordid story of armed men against the defenceless; but everywhere in the gloom shine out deeds that will stir the hearts of men so long as they admire courage dauntless and sustained.

TABLE I.

*Ships and Tonnage Sunk by Submarines, 1917-8*

A = Number of British and Allied merchant ships and fishing vessels sunk by submarines.

B = Number of neutral merchant ships sunk by submarines.

C = Total gross tonnage in thousands of tons.

D = Number of German submarines sunk.

**SUCHOW**, China (see 26.7), with a population of about 500,000, is a manufacturing centre. Since the opening of the port some industrial establishments have been started on European lines. In 1911 the colleges of Shanghai and Suchow were united, and are established as Suchow University on a large campus; negotiations were in progress in 1924 for the co-operation of the university and other institutions of eastern China in the management of legal and medical schools. A municipal council was formed in 1920.

**SUDAN, ANGLO-EGYPTIAN** (see 26.10).—Its status is defined by the Anglo-Egyptian convention of 1899 made after its re-conquest by the joint efforts of the British and Egyptian Armies. According to this convention an Anglo-Egyptian condominium was established over the Sudan and the administration placed in the hands of a governor-general to be nominated by the British Govt. and appointed by a royal decree of Egypt. This secures British predominance in the administration. Area 1,014,600 square miles. The population in 1921 was estimated at 4,853,000.

## I. POLITICAL HISTORY

*Pre-War Period.*—Until a few years before the War the Sudan was little known and its possibilities were not fully realised. Great progress was made under the administration of Sir Reginald Wingate and his lieutenants, the results slowly becoming apparent in the agricultural development, increasing trade and added security. In 1911 experiments were started in the area lying between the White and Blue Niles, known as the Gezira, with the object of ascertaining whether long-staple cotton could profitably be grown. Early in 1912 the railway from Khartoum to El Obeid was completed, thus bringing the Gezira area within easy reach of Khartoum, and making the resources of the rich gum and cattle areas of Kordofan more fully available. In the same year the land settlement and cadastral survey of the Gezira, undertaken with a view to safeguarding native rights therein, was finally completed.

By that time the possibilities of cotton growing had been more fully realised, and the matter was energetically taken up by the British Cotton Growing Association. Delegates, headed by the chairman in person, visited the principal cotton areas early in 1912, and reported their conviction "that in the Anglo-Egyptian Sudan there is one of the very finest cotton-growing propositions in the whole of the British Empire, both for Egyptian and American cotton. There are almost boundless possibilities for the future." Shortly after the return of the delegates to England an influential deputation waited on the British Govt., and urged the desirability of guaranteeing a loan for cotton development. As a result an Act was passed in 1913 giving parliamentary sanction for a guarantee of £3,000,000, of which £2,800,000 was to be applied to irrigation of the Gezira and railway extensions, and £200,000 to other irrigation projects in the neighbourhood of Kassala (the Gash delta) and Tokar (the Baraka delta).

The foundations of the Sudan's economic career were thus laid, but the completion of the projects then planned was delayed for many years by the outbreak of the World War. Just at this time (1913-4) the value of any project for giving to large areas the certainty of adequate water supplies by means of artificial irrigation received a striking demonstration. In 1913 rains were very bad and the river flood was the lowest recorded for more than a century so that all over the Northern Sudan, and particularly in the Gezira area, famine conditions obtained during the following winter. The situation was saved by the Government importing corn from India, and it is probable that this contributed more than any other factor to the quiet that prevailed in the Sudan during the four years of the War.

*War Period.*—Fortunately rains and Nile flood alike were excellent in 1914 and, except in Darfur, the outbreak of War excited no great attention in native circles. The province of Darfur, some 142,500 sq. m. in extent, lying about three weeks' journey west of Khartoum, had never been administered nor visited by any official of the Government since the re-occupation of the Sudan, but had been left in charge of a native sultan, owing nominal fealty to the Sudan Government. This Sultan, Ali Dinar, adopted an aggressive attitude in 1915, and his warlike preparations at the beginning of 1916 made it imperative to suppress him before he took the offensive and invaded the neighbouring province of Kordofan. An expedition was therefore despatched to Darfur, under the command of Lt.-Col. P. V. Kelly, and a crushing defeat inflicted on the Sultan outside his capital of El Fasher on May 22 1916. The Sultan fled with the remnants of his army and was killed in the following November. The country then rapidly settled down, and, with the exception of a fanatical outbreak which occurred in the south of the Province in 1919, administration progressed smoothly and successfully on the same lines as in the rest of the Sudan. The western frontier of Darfur,

which had been a bone of contention between the British and French Govts. ever since the days of Fashoda, was the subject of negotiations between the two Powers in 1919 and again in 1923. After the completion of a joint survey of the whole boundary from, approximately, lat. 5° N. to lat. 19° N. a settlement was finally embodied in a Protocol during Jan. 1924.

*Post-War Period.*—Within the Sudan the immediate political results of the War, apart from the Darfur expedition, were relatively unimportant. The ultimate effects were still difficult to gauge in 1925. That the world cataclysm should have no reactions in the Sudan was out of the question, and the economic development of the country, which, at the close of the War, at once brought it into close touch with European thought and European markets, rendered any such idea doubly impossible. Moreover, the intellectual ferment into which Egypt had been plunged as a result of the War, the political disturbances of 1919, and the Press agitation engineered by Egyptian Nationalists for the ejection of the British from the Sudan and its incorporation with Egypt had their effects, and the national self-consciousness which is dormant in every race showed signs, under Egyptian instigation, of awakening among that section of the Sudanese, town dwellers for the most part, which by education and contact with outside influences tended naturally to be receptive of new ideas. Happily 1920 was a year of prosperity, rich harvests and increasing trade, and the interests of the classes in question was largely centred on money making and the possibilities of the Gezira Irrigation Scheme, on which preliminary work was being actively prosecuted.

Legitimate aspirations in the political field, however, were not ignored. Late in 1920 the Milner Commission, which, though primarily appointed to inquire into the causes of the disorders in Egypt and to make recommendations as to the future constitution of that country, had also touched in its report upon the question of the Sudan, expressed the opinion that the "present administration is popular in the Sudan and, with few exceptions, peaceful and progressive conditions prevail throughout the country." At the same time a warning was issued against undue centralisation, and a policy of "decentralisation and the employment, wherever possible, of native agencies for the simple administrative needs of the country" was advocated. This policy was not in fact a new one, but its reassertion by so authoritative a body undoubtedly exercised a revitalising effect, and considerable strides were subsequently made in the direction recommended.

The only disturbance to an ordered and healthy course of political evolution in the Sudan, came as a reaction from political disturbances in Egypt. The Milner Commission recommended that whatever change was made in the relation between Great Britain and Egypt, British predominance in the Sudan should not be affected. Accordingly when in Feb. 1922 the independence of Egypt was declared, provision was made for the maintenance of the "status quo" in the Sudan, and the Sudan was included as one of the four matters reserved for future negotiations between Great Britain and Egypt. It soon became clear, however, that the grant of independence to Egypt was to be followed by further demands, and the Nationalist party under Zaghloul adopted as one of its principal political cries the claim that the independence of Egypt was meaningless without the independence of the Sudan, meaning by "independence" in the latter case subordination of the Sudan to Egypt.

An active campaign of Anti-British propaganda and intrigue was conducted from Egypt in the Sudan, where the position was complicated by the fact that the whole military garrison of the country was furnished by the Egyptian Army, consisting partly of purely Egyptian units but mainly of locally recruited units officered by Egyptians and Sudanese with a small addition of British officers. It would have been idle to expect that all the seed then sown would fall on barren ground. The really remarkable fact was that so little germinated. A "White Flag League" with funds and motive power drawn from Egypt, but with a membership composed for the most part of young Sudanese, had been started in the Sudan, and, as a result of its activities, a few minor disturbances occurred in Omdurman, Khartoum, Port Sudan, Atbara and elsewhere. More important incidents were mutinies of the Egyptian Railway Battalion at Atbara, and of the Sudanese cadets of the military school in Khartoum, in Aug. 1924, but the country as a whole remained staunch and viewed these manifestations with distaste or indifference.

Concurrently with these local developments correspondence had been passing during the summer of 1924 between the British Prime Minister (Mr. Ramsay MacDonald) and Zaghloul for arranging conversations to discuss the four points which had been reserved in the declaration of 1922 for further discussion. These conversations finally took place in Sept. and Oct. and ended abortively. The British Prime Minister then addressed a despatch<sup>1</sup> to the British High Commissioner in Cairo laying down very clearly the position and policy of the British Govt. in relation to Egypt and the Sudan. The following passage may be quoted:—

<sup>1</sup> Cmd. 2269 of 1924.

... In the meantime, the duty of preserving order in the Sudan rests, in fact, upon His Majesty's Government, and they will take every step necessary for this purpose. Since going there they have contracted heavy moral obligations by the creation of a good system of administration; they cannot allow that to be destroyed; they regard their responsibilities as a trust for the Sudan people; there can be no question of their abandoning the Sudan until their work is done. His Majesty's Government have no desire to disturb existing arrangements, but they must point out how intolerable is a *status quo* which enables both military and civil officers and officials to conspire against civil order, and unless the *status quo* is accepted and loyally worked out until such time as a new arrangement may be reached, the Sudan Government would fail in its duty were it to allow such conditions to continue. His Majesty's Government have never failed to recognise that Egypt has certain material interests in the Sudan which must be guaranteed and safeguarded—these being chiefly concerned in her share of the Nile water and the satisfaction of any financial claims which she may have against the Sudan Government. His Majesty's Government have always been prepared to secure these interests in a way satisfactory to Egypt. I have in the preceding paragraphs defined the position which His Majesty's Government are compelled to take up in regard to Egypt and the Sudan and which I conceive it to be my duty to conserve unimpaired.

The failure of Zaghloul in London left him without any constructive policy for dealing with the Sudan, and the forces of disorder asserted themselves. On Nov. 20 1924 Sir Lee Stack, the Governor-General of the Sudan, succumbed to a murderous attack made on him in the streets of Cairo. An ultimatum was at once presented by the British Govt. and among its terms was the immediate withdrawal of all Egyptian troops from the Sudan, *i.e.*, all purely Egyptian units and the Egyptian officers of the Arab and Sudanese units. The demand was refused, and on Nov. 23 orders were issued for their compulsory evacuation. Some of them departed without demur; others adopted an attitude of passive resistance. At this stage some black Sudanese detachments stationed in Khartoum, probably misunderstanding the exact position of affairs, and certainly instigated by the Egyptian officers and by sympathisers among their own officers, mutinied on Nov. 27; and it was not until the 29th that order was restored. In outlying districts the evacuation of Egyptian troops took place without trouble except one incident at Talodi, which ended with no loss of life.

The evacuation of the Egyptian units and personnel was followed by the creation of a Sudan Defence Force, consisting of Sudanese and Arab units which had hitherto been incorporated in the Egyptian Army and which, in the new force, undertook allegiance solely to the Governor-General of the Sudan. By the end of the year conditions had been restored to normal. The Egyptian troops had gone, a number of Egyptian officials, whose political sympathies with their motherland had led them into excess, had been deported, and the country settled down with relief to the ordinary business of life. The disturbances had been limited to the few urban centres and had never had any effect on the country as a whole. In Jan. 1925 Sir Geoffrey Archer, the newly appointed Governor-General, arrived from Uganda. At the close of 1925 the country was peaceful and contented.

## II. ECONOMIC HISTORY

The economic progress of the Sudan after 1914 was largely the result of the development of certain large projects for the growing of long staple cotton under irrigation in the Gezira, Kassala and Tokar areas, the increasing export of gum, and the general improvement of agriculture in the southern areas where the rainfall is sufficient to produce regular crops of cotton, sesame, ground nuts, etc. Work on the Gezira irrigation project, for which the British Govt. had in 1913 agreed to guarantee a loan for £3,000,000, was suspended during the War and resumed in 1919. Costs of all material and labour having doubled, the amount asked for was increased to £6,000,000, the guarantee by the British Govt. authority being given by the Sudan Loan Act of 1919. This amount once again proved an underestimate and by successive loan Acts, the authorised sum was increased to £13,000,000, of which about £12,000,000 was required for the Gezira scheme itself. The scheme was successfully completed in July 1925 and an area of about 160,000 ac.

put under cultivation, of which 80,000 ac. are under cotton, 40,000 durra and 40,000 Lobia (a green crop). By the 1926 season the total canalised area of the original project was available, i.e., 300,000 ac., of which 100,000 will be under cotton, 100,000 under food crops and 100,000 fallow. This project will have a very great effect on the economic position of the country. A moderate estimate of the average value of the cotton crop is £E.2,000,000. The work is being carried out on the basis of a partnership arrangement between the Government, the Sudan Plantations Syndicate and the native cultivators. The latter receive the whole of the food crops and 40% of the value of the cotton crop and get land and water free.

The Kassala cotton area consists of the delta of the inland river Gash in the Eastern Sudan, some 60 m. long by 10 to 20 m. wide. A railway giving direct access to the sea was essential to the development of the area, and in 1922 a loan of £1,250,000 was authorised, guaranteed under the Trade Facilities Act by the British Govt., for the building of a railway from Haia Junction near Thamiam station on the Atbara-Port Sudan Line, to Kassala. This line was completed in 1925. The exploitation of the area is being carried out by the Kassala Cotton Company under an arrangement similar to that of Gezira. In the Tokar area cotton is grown between the Red Sea mountains and the coast. The natural conditions are similar to those at Kassala. The value of the crop for 1924-5 was about £500,000. A short railway line used for the transport of the crop connects Tokar with Trinkitat harbour on the Red Sea. In addition to these projects steps have been taken since 1922 to encourage the development of rain grown cotton in the central and southern districts. These had not yet produced large results up to the end of 1925, but returns were steadily increasing. In 1925 cotton exports from the Sudan were valued at £E.1,636,784. Apart from cotton the most important export is gum arabic; the average value of total exports of this product for the period of 1923-5 was £E.881,811, as compared with an average of £E.470,220 for the period 1911-3.

The general growth of trade and production is shown in the following tables:—

External Trade

|      | Imports    |           | Exports and Re-exports |
|------|------------|-----------|------------------------|
|      | Government | Public    |                        |
|      | £E.        | £E.       | £E.                    |
| 1913 | 504,176    | 1,605,300 | 1,278,841              |
| 1922 | 1,696,535  | 2,556,355 | 2,298,770              |
| 1923 | 1,694,779  | 2,974,225 | 2,758,425              |
| 1924 | 1,820,210  | 3,654,700 | 3,830,171              |
| 1925 | 1,609,317  | 3,828,410 | 4,168,364              |

**Communication and Transport.**—The extension of the Halfa-Khartoum railway line to El Obeid, and the construction of the branch to Kassala were of immense importance to the development of the country, which depends very largely upon the extension of transport facilities. The Atbara-Port Sudan line is taking an increasing quantity of both exports and imports, the traffic via Halfa and the Egyptian railways having greatly decreased since 1910, particularly since the abolition of the British Protectorate over Egypt. Port Sudan had, by 1925, become a regular port of call for ships travelling through the Red Sea; its increasing trade is shown by the following table:—

Shipping at Port Sudan

|      | British Vessels | Tonnage   | Foreign Vessels | Tonnage | Total Vessels | Total Tonnage |
|------|-----------------|-----------|-----------------|---------|---------------|---------------|
| 1908 | 191             | 269,626   | 40              | 84,625  | 231           | 334,251       |
| 1913 | 242             | 527,845   | 72              | 194,025 | 314           | 721,870       |
| 1922 | 342             | 1,138,601 | 110             | 361,334 | 452           | 1,499,935     |
| 1923 | 456             | 1,768,603 | 153             | 496,772 | 609           | 2,265,375     |
| 1924 | 513             | 1,940,266 | 186             | 582,963 | 699           | 2,523,229     |

**SUESS, EDUARD** (1831-1914), Austrian geologist (see 26.21), died at Vienna April 25 1914.

**SUEZ CANAL** (see 26.22), the waterway linking the Mediterranean Sea with the Gulf of Suez in the Red Sea. It was obvious in 1909 that the Suez Canal must be recognised not only as an essential waterway of the world, but also as a permanent factor in the commercial and political association of the East and West. The company, therefore, decided to approach the Egyptian govt. with a request for the prolongation of their concession, which was due to expire in 1968, on terms that appeared exceptionally favourable to Egypt.

That view was not shared, however, by the Egyptian parliament, which unanimously rejected the terms offered by the company and the request for an extension of their lease. But this fact had no untoward influence, either upon the shares of the company or upon the sea-borne trade entrusted to it. On the contrary, the traffic through the canal continued to increase until the outbreak of the World War in 1914, which utterly changed the character of the administration and purpose that had hitherto been associated with the name of the company. In consequence of the hostilities, the entire defence and direction of the canal—its enormous plant and its expert personnel—was handed over to the British military authorities. The canal became the strategic frontier of Egypt, guarded by the armies and navies of France and of the British Empire. Its waterway was open to the ships of Allied and neutral powers for the whole of those four eventful years, except during a few hours of fighting on Feb. 3 1915 when a Turkish Army that had marched across the desert from Damascus to invade Egypt was routed—never to return. From end to end the banks of the canal resembled one long armed camp, of which all traces had in 1925 disappeared; and the only signs visible to future generations of that great upheaval will be the three War monuments at Port Said, Ismailia and Suez, and the railway which Lord Allenby laid from Kantara to Jerusalem for the subjugation of Palestine.

The figures show how much the canal suffered commercially during the War, and also how plainly the subsequent reaction proved its necessity for the wellbeing of the world. In 1912 5,373 ships, with a net tonnage of 20,200,000, passed through the canal. In that year the receipts amounted to 140,000,000 francs and the expenditure to 47,500,000 francs in round figures. By the year 1917 the traffic through the canal had gradually dropped to 2,353 ships, with a net tonnage of 9,000,000; the receipts were reduced to 72,000,000 francs and the expenditure to 37,000,000 francs. After peace was declared in 1918 the reaction immediately set in: statistics for 1919 show that close on 4,000 voyages were made through the canal, representing a total of 16,000,000 tons; the receipts for that year were 184,500,000 francs, and the expenditure amounted to 42,000,000 francs. The figures 1924 show that during that year 5,122 ships, with a total net tonnage of 25,000,000, passed through the canal, the receipts amounting to 508,500,000 francs and the expenditure to 60,000,000 francs. The depreciated value of the franc is largely accountable for the huge total recorded as receipts in 1924, since the Suez Canal Company convert all their takings from Egyptian francs (at 25-20 to the £E.) into French francs.

**Improvements: Canal.**—Since the War, the engineering programmes, which had been seriously interrupted, have been taken in hand with redoubled vigour. The 1912 programme has been completed, and the 1923 programme is already in advance of its time schedule. These programmes include the building of jetties and of "bassins," and the widening, deepening and straightening of the canal, a process which will be continued until the two largest ships that use Eastern and Far Eastern ports can cross one another in the canal without tying up.

Another great improvement is the creation of a new city opposite to Port Said, to which the name of Port Fuad has recently been given. To this new centre of activity all the company's engineering and repair shops were transferred, an operation which greatly reduced the congestion in Port Said. On this, the Asiatic side of the canal, all the employees and workpeople now resident in Port Said will eventually live; and in this hope the company drew up a

far-reaching scheme for a kind of garden city with avenues and boulevards, shops and schools, hospitals, churches and mosques, and with dwelling houses and apartments suitable for all classes of a very international community.

Some 12,000 persons (including wives and children) are dependent upon the company for their maintenance in Egypt—that is to say, from Port Said to Suez. Between the highest and lowest grades of these we find superintendents, doctors, architects, schoolmasters, priests, nuns, clerks, pilots and representatives of every rank in the organisation of industry, down to the native labourer. For all of these the company has the greatest care: a minute study of the detailed accounts for any one of recent years will convince the most scrupulous sociologist or socialist, that few companies give such unrelenting attention to the wellbeing of their personnel. It is certain that, in Egypt, no body of employees or of workmen enjoy such comfortable circumstances. Since the War salaries have been raised, sick pay increased, an eight-hour day instituted, holiday pay and free tickets granted to the servants of the company and their families without distinction of grade or nationality; and a co-partnership scheme has been created, to which all are admitted and thereby become entitled to a share in the profits of this great undertaking. The company also provides its people with cheap houses, free dispensaries, hospital accommodation, co-operative stores, schools, sports and—most important of all—with a plentiful supply of filtered fresh water at the price of 50 centimes a ton. Under these exceptional conditions, service with the company is as eagerly sought for in Egypt as in France; and, whilst labour and other political troubles were rife throughout Egypt in 1919 and 1920, they scarcely created a ripple of disturbance on the calm social waters of the Suez Canal administration.

**Control and Finance.**—It will be seen that there is no foundation for the prevalent idea that it is a British undertaking which belongs to the British Govt., even though the British Govt. holds (as has already been shown) seven-sixteenths of the shares. The company is, as a matter of fact, French through and through for purposes of administration. On the board of management there are 1 Dutch, 10 British and 20 French directors, and they work in closest harmony together. Of the ten British directors, three represent the British Govt. in respect of their large holding of shares, and seven represent the shipping and commercial interests of Great Britain, which now supplies about 60% of the total traffic through the canal. Next in order of importance comes the Dutch mercantile marine, with 10% of the total; and third on the list we find Germany (whose flag was not seen on the canal between 1915 and 1920) providing 6.5%, France 6% and so on. The capital sum (£4,000,000) invested by Great Britain in Suez Canal shares in 1875 has been repaid about eight times in dividends and interest. In 1922 His Majesty's Govt. received £892,000; in 1923, £1,016,000, and in 1924, £1,167,000, free from all taxation at the source. The French Govt. owns no shares in this pre-eminently French enterprise, but it benefits to no small degree by the prosperity of the company, whose business was taxed in 1925 to the extent of about 42,000,000 francs.

M. Ferdinand de Lesseps' great undertaking has fully justified its existence. It is upon the facts stated above, rather than upon the present value of the shares (i.e. 14,000 francs, on Dec. 4 1925, for a share whose face value was 250 francs) that the company base confident hopes for their continued prosperity and usefulness until their lease from the Egyptian Govt. expires. **SUGAR:** see CONTROL, INTER-ALLIED; FOOD SUPPLY.

**SUK, JOSEF** (1874– ), Czech composer, was born at Křečovice Jan. 4 1874. He attained maturity almost at the very outset of his career and his compositions are distinguished more for their quality than for their number. All his work is marked by a finished skill, both of content and form. In his resourceful harmonisation and varied rhythm he showed himself a follower of the tendencies inaugurated by Dvořák. He wrote compositions for piano, violin, cello and orchestra. His symphonic poem "Prague" is an elaborate evocation of the glory of the Czechoslovak capital. His symphony "Asrael"

and the symphonic poem, "A Summer Legend," are of an elegiac character. Suk excelled also in vocal compositions, both for male and female voices. His most noteworthy work is that entitled "Ripening," which, in three sections, Life, Work and Love respectively, expresses his own emotional development. He was one of the founders of the Bohemian Quartet, and in 1922 became professor at the Master School for composition at the Prague Conservatoire, where he had studied under Bennewitz, Stecker and Dvořák.

**SULGRAVE MANOR**, the early English home of the ancestors of George Washington. Situated 2½ m. northwest of Helmdon in Northamptonshire, it has come to be recognised as a shrine for all patriotic Americans and thoughtful English folks to visit. Laurence Washington, twice mayor of Northampton, bought the property from King Henry VIII. in 1539, on the dissolution of the smaller religious houses. It had previously belonged to the priory of St. Andrew, Northampton. Laurence Washington, from whom George Washington was seventh in direct descent, and his children and grandchildren lived in the manor house until 1610.

The place, therefore, carries the history of the Washington family back to the days of Henry VIII. and the English Reformation, and antedates Mount Vernon, George Washington's home in Virginia, by 200 years. It was purchased, in Jan. 1914, for £8,400, by the British committee for the celebration of 100 years of peace between Great Britain and the United States (1814–1914), and the whole property, including the contents of the manor house, is vested in three ex-officio trustees: the American Ambassador in London, the British Ambassador in Washington and the regent of the Mount Vernon Ladies' Association of the Union. It is administered and controlled by the Sulgrave manor board, a body formed to carry on the work of the British peace centenary committee in perpetuity. The manor house has been partially restored to its original condition, and tastefully furnished with choice furniture of the period. A portion of the grounds has also been laid out. At the conclusion of this preliminary work, a formal reopening and dedication took place, on June 21 1921, in the presence of a large Anglo-American gathering.

The portion of the house restored is the oldest part, the south or Tudor wing. On the south gable are the royal arms of the Tudors; and in the right spandrel of the arch of the main doorway, the Washington Arms, three mullets and two bars, which were the inspiration of the Stars and Stripes, the American national flag. The building is, therefore, one of rare historical interest, and every care is taken by the Sulgrave manor board to preserve its distinctive character and atmosphere. The furnishings are, for the most part, gifts from both British and American donors, and include an original Gilbert Stuart portrait of George Washington and many other treasures. (L. OF F.)

**SUMMER SCHOOLS** (see 6.19).—The introduction of new subjects into the curriculum and the development of new teaching methods are responsible for the growth of summer schools and vacation courses for teachers.

**History of Movement.**—Among the earliest must be mentioned the one carried on at Naas in Sweden and attended by teachers who desired to learn Sloyd as an introduction to handwork. A course on somewhat different lines was introduced and conducted at Leipzig by Dr. Goetze, and in the latter part of the 19th century these courses attracted many teachers from England and America during the summer vacation. The progress of handwork in English schools soon led to the establishment of summer courses under the direction of the Educational Handwork Association.

#### I. IN GREAT BRITAIN

In a less specialised field, the University Extension Movement had established summer meetings held alternatively at Oxford and Cambridge. These were attended by many teachers, although designed primarily to meet the needs of students in University Extension classes. The Science and Art Department, now merged in the Board of Education, provided holiday courses for selected teachers in various branches of science; and certain

French universities organised summer classes in French language and literature which attracted teachers of modern languages.

**Present Organisation.**—From these beginnings the movement developed rapidly, and the provision of summer schools and vacation courses became extremely liberal, although it does not yet cover the whole ground or meet the needs of all teachers. The courses offered present great variety alike in their curriculum and organisation. Some extend over a month, while others last only a fortnight, or even a week. Some are specialised in character, as, for example, a course dealing with the teaching of Latin; while others cover a wider range and aim at supplying form teachers in secondary and elementary schools with information concerning new developments in school organisation and in general method. The Board of Education continues to provide courses for selected teachers who receive financial aid in the shape of a grant and attend lectures and demonstrations in such subjects as rural education, modern languages, science, geography and history. Music also receives considerable attention, and every summer vacation sees a large number of teachers of music attending the courses provided in their subject.

**Features of Summer Courses.**—A well-arranged course is not confined to lectures and demonstrations—it provides opportunities for social intercourse and for free discussion, and some of the most successful courses are held in university towns, where the students live for a time in a college and enjoy the amenities of the playing fields and the river. A very popular course, which is held in London under private auspices, aims at giving to teachers from the provinces and from abroad an intimate knowledge of the chief attractions of London and of hearing addresses from eminent men and women, besides providing courses of lectures on modern lines.

**Courses for Teachers.**—It is now generally accepted that teachers should be encouraged in every possible way to refresh their minds and revivify their work by attending summer schools. It is recognised, however, that for many teachers the best refreshment is a complete holiday, and some of the courses arranged are therefore held at times outside the holiday period, the teachers being granted leave of absence to enable them to attend. This plan calls for the co-operation of the local authority and the Board of Education, and this is held to be justified on the ground that the work of the teacher gains in efficiency and therefore brings a return in public service. In England the practice of giving a "Sabbatical year" has not been widely adopted, although in some universities certain professors or lecturers have been granted leave of absence for a term or more to enable them to pursue definite lines of research. It is increasingly held, however, that the continued efficiency of school teachers demands that some arrangement should be made by which they may have the opportunity of bringing their studies up to date. The report of the departmental committee on the training of teachers recommended that teachers of experience should be granted leave of absence in order that they might attend university courses on education, and thereby equip themselves for posts of responsibility in the educational service.

## II. IN THE UNITED STATES

The long summer vacation which interrupts the work of schools in the United States during the months of July and Aug. is a survival of the period when the population was very largely agrarian and there was a demand during the harvesting period for the labour of young people. With the readjustment of industrial and economic conditions, the summer vacation has come to be recognised as undesirably long. In spite of this fact, the sessions of public schools continue to follow established tradition. Various devices have been suggested for the utilisation of the summer months. A number of school systems have organised elementary vacation schools, where a programme of supervised play and handwork is carried on. In a few cases the regular programme of studies has been conducted in what is known as the all-year school. Summer schools at the elementary level are, however, relatively rare. They are somewhat more common in secondary schools. Here they serve most frequently the purpose

of offering opportunity to backward pupils to make up their deficiencies. They furnish, however, to some extent an opportunity for shortening the period of high-school attendance for those who wish to complete their work as fast as possible.

It is in the fields of adult education and of higher education that the summer school has achieved its most distinguished success. In its earliest form the summer school provided series of lectures and entertainments intended to supply adults with an opportunity for intellectual recreation during vacation. Chautauqua, N. Y., was the home of the largest and most influential school of this type. From Chautauqua the practice of adult education spread, and the word chautauqua has become current as the designation for almost any course of lectures, whether given in the summer or winter, whether lasting for six weeks or three days. Chautauquas are now common as community enterprises and as enterprises sponsored by churches and schools.

**University Activity.**—It is significant that the first proposal for a summer session of a university came from a man who had been intimately associated with the Chautauqua movement, William Rainey Harper. When President Harper organised the University of Chicago in 1892, he planned its session in four units of twelve weeks each, and arranged that one of the sessions should fall in the summer covering the weeks during which most schools and colleges have their summer vacation. President Harper's idea was scoffed at in many quarters by those who believed that summer study would degrade academic standards. The movement to establish such sessions in universities, however, spread, until they became very common. At first the institutions which held summer sessions limited them to six weeks, and the University of Chicago was practically alone in its efforts to conduct four full quarters of work. During the period of the World War a great stimulus was given to the summer school, because it was recognised that economy of plant and of the student's time could be effected by holding summer sessions. A number of the war boards urged institutions to keep their doors open throughout the year, and as a result several of the larger institutions, especially among the state universities, responded favourably. A poll of 31 leading universities showed the following facts regarding length of summer sessions:—

|                                      |    |   |   |    |    |    |
|--------------------------------------|----|---|---|----|----|----|
| Number of weeks in session . . . . . | 6  | 8 | 9 | 10 | 11 | 12 |
| Number of institutions . . . . .     | 10 | 4 | 1 | 3  | 10 | 3  |

**Types of Students.**—The student body of summer sessions is seldom recruited from the regular undergraduates. The typical undergraduate, accustomed through the high-school period to a long interruption of his study in the summer, demands a summer vacation. Graduate students, pushed by the urge to secure a higher degree as early as possible, not uncommonly take advantage of summer sessions. The great majority of the summer student population is made up of teachers and school administrators who during the other three quarters of the year are professionally engaged in school work. It has come to be a very common practice for boards of education either to require summer study of their employees or to reward such study by special salary inducements. A large number of institutions other than universities hold summer sessions. Normal schools almost universally do so. The aggregate number of students in the summer schools of higher institutions is large. Thirty-one universities reporting for eight years show an increase from 36,971 students in 1918 to 87,208 in 1925. In some of the states it is reported that 80% of the teachers attend regularly summer sessions either in normal schools or colleges or universities. (C. H. J.)

**SUMMER TIME:** see DAYLIGHT SAVING.

**SUN:** see ASTRONOMY; SOLAR ENERGY.

**SUN CURE:** see HELIOTHERAPY.

**SUNDERLAND**, England (see 26.100), with an area of 3,357 ac. and a population of 159,055 in 1921, is a great shipbuilding centre and has a large coal trade. New libraries have been opened in Hendon, Monkwearmouth, and in the western district of the city. The parish of St. Aidan's, Grange town, was formed and the church partially finished and consecrated in 1911; and the church of St. Gabriel's, Monkwearmouth, was built in 1912.

Backhouse Park of 13½ ac. was presented in 1923, and a War memorial has been erected in Mowbray Park. The south breakwater at the harbour entrance has been extended, making the pier 2,844 ft. long; the area of the harbour, which has been enlarged by dredging, is about 150 ac. A large dry dock, 515 ft. long, was opened in 1925.

**SUN YAT-SEN** (1867-1925), Chinese republican leader. Dr. Sun (known in China by the more familiar title of Sun Wen) may truly be described as the Father of the Chinese Republic. His father, a poor farmer living at Hsiang Shan near the Island of Macao, was a convert to Christianity (under the London Missionary Society) and his son early espoused the Christian faith and continued to describe himself as a Christian till his death, before which he gave instructions that he should be buried with Christian rites. Another influence of his early years came from his uncle who had fought in the Taiping rebellion and who was the village schoolmaster at his birthplace (Hsiang Shan).

At 18 years of age he was employed at the mission hospital in Canton and had already acquired some knowledge of the English language from an English lady. In 1891 he entered upon a medical course at the newly formed medical school in Hongkong of which he was the first graduate in 1894. It was here that his life-long friendship with Sir James Cantlie began. Through a Chinese fellow student, Dr. Sun came into association with a secret society which was planning to overthrow the existing régime in China and which offered to assist him in the carrying out of the plans which were already developing in his mind. The first of a number of definite revolutionary efforts with which Dr. Sun was associated was brought to light in 1895. The other members of the group concerned with this attempt were executed, Dr. Sun alone escaping with his life. Thus began that long period of Dr. Sun's life during which he was working outside his native country with the object of bringing about a revolution. In all, 10 abortive attempts were made. Dr. Sun worked indefatigably during these years, taking three trips to Europe, four to the United States, five to Japan and also visiting the East Indies and Straits Settlements and Honolulu on several occasions. In the latter place, shortly after the Chino-Japanese War in 1895, he established Hsing Chung Hui, the forerunner of later revolutionary organisations. Of these the most important was the Tung Men Hui formed in Japan with the help of General Hwang Hsing. In 1898 he determined upon those principles which he later announced and expounded at great length. The three fundamental principles were Nationalism, Democracy and Socialism, and the five spheres in which they were to be worked out were: the executive government, the legislative field, the judicial field, the civil examinations and the department of censorship or impartial scrutiny of public matters and officials.

It was not, however, until 1905 that Dr. Sun publicly declared his adherence to these ideas and worked them out in fuller detail. Immediately following the Boxer outbreak in 1900 Dr. Sun attempted to use the reaction as a means of establishing a democratic government and ending the Manchu régime, but this attempt as others proved abortive. In 1905 the Chinese Revolutionary League was formed in Europe and Japan and through this Dr. Sun enlisted the support of a great number of Chinese not resident in China. Dr. Sun raised during this period large sums of money among adherents to the revolutionary cause and was thus able to spread his ideas through secret agencies in China itself. His activities brought him into prominence and a large price, finally amounting to £100,000, was placed upon his head. On one occasion in 1896 he was kidnapped while in London and held at the Chinese Legation for several days. His release came about through a note to Sir James Cantlie, which was smuggled out of the Legation and which led to Lord Salisbury taking the matter up as one of privilege.

In 1911 the revolution broke out in China which was to sweep away the effete Manchu leaders and to set up, in name at any rate, the new Republican form of Government. Dr. Sun's personal influence had much to do with the inner organisation of this revolt, and in particular with the form in which an alternative to the Manchu régime was presented to the nation. While

there was a widespread feeling that the dynasty had outlived its usefulness, there was little understanding of what was involved in establishing a republic and only the efficient organisation of the Kuo Ming Tang (Dr. Sun's creation, known as the Republican party) was able to turn the anti-Manchu tide into a pro-republican movement. Dr. Sun was in England when the revolution began and was called back to China as soon as it became general. On Jan. 5 1912 he took the oath of office as Provisional President of the new Republic, this position having been offered to him by the National Convention which was then meeting in Nanking.

On Feb. 12 an Imperial Edict announced the abdication of the Emperor and the substitution of republican for monarchical Government. Yuan Shih-K'ai was entrusted with the task of carrying through the changes involved, and Dr. Sun, realising the impossibility of uniting the country under his own presidency and in hopes of unity being attained under Yuan, resigned his presidency in favour of the latter. He accepted the post of Director-General of Transport and Trade and in this position made some study of the constructive side of the task involved in making a new China. He travelled widely throughout the country, being no longer a suspected traitor but the honoured Father of the Republic. He was, however, always more of the propagandist and inspirer than the practical administrator.

He became increasingly restless under the leadership of Yuan Shih-K'ai, and in 1917, after the latter's coup d'état and death, he put himself at the head of a movement for an independent republic of South China. The strength of his support had always been drawn from Kwang-tung province and here he might have remained within his own group had he been able to work with others and content to develop one part of China, leaving the rest to go its own way. However, he soon found it impossible to co-operate with the military leaders in Canton and he resigned from his position as President of the Republic of South China. The military régime was maintained largely by Kwang Si troops until 1921 when Ch'en Ch'ung-ming drove them out and called in Dr. Sun again.

The following year he determined on an advance in force against the north, while Ch'en Ch'ung-ming desired to consolidate the work begun in the province of Kwang-tung. This led to an open breach and Dr. Sun was once more driven from his native province, finding refuge in Shanghai. In Feb. 1923 he called to his aid troops from Kwangsi and Yunnan and thus defeated his one time colleague and subsequent rival, General Ch'en. From that time until his death he was acknowledged as the chief executive of the Province, but his effective sway did not extend far beyond Canton and even there was maintained only by the use of the troops from elsewhere. He used and permitted very violent methods, more particularly in the attack upon the Merchants Volunteer corps and the looting and burning of a considerable part of the city of Canton in March 1924. In these ways he lost much of the support which had been given to him and to the Kuo Ming Tang by Chinese overseas. At the same time his pronounced socialist views ensured him the support of the mass of the workers and on a number of occasions he used his influence to secure higher wages for labourers, particularly when strikes were declared in Canton.

So far as local support was concerned Dr. Sun's star seemed to be declining in the autumn of 1924, but he was still idolised by the student class and in his own party where his was a name to conjure with. It was then that Feng Yü-hsiang brought about his coup whereby Wu Pei-fu (a determined enemy of Dr. Sun's) was routed and Chang Tso-ling co-operated with Feng to put the old Anfu leader Tuan Ch'í-jui in the position of Chief Executive in Peking. Dr. Sun had been cultivating friendly relations with the parties now predominant, and he was called to Peking to confer with them in regard to the calling of a people's conference and other matters connected with the establishment of the new régime. For some time past his health had been failing with the growth of what proved to be cancer of the liver and he finally succumbed to this complaint on March 12 1925, shortly after reaching Peking. Time was sufficient however again to reveal the

difficulty which Dr. Sun always had in co-operating with others, particularly those who did not fully share his ideals. A serious difference over the method of calling the conference had developed and Sun Yat-sen's death seemed the only thing to prevent open hostility.

Dr. Sun left behind him two wills which have been very widely distributed and commented upon in China, one concerning his personal effects, a very simple document; the other a re-affirmation of the principles by which his life had been guided and an expression of his desire to see these carried out after his death in the reconstruction of China. Dr. Sun was a man of outstanding personality, and one whose position came to be recognised throughout the whole of China. It would be no exaggeration to say that before his death he was recognised as the leading figure in the country, even those who criticised him most severely recognising the contribution which he had made to the new order and the power which his personality had exercised upon his fellow countrymen. This he owed to his sincerity, single-mindedness and courage. He was kind-hearted and an eager student, humble-minded and patriotic. His ambition was for China rather than for himself. By his personal charm he won to his side many who did not fully share his theories.

Nevertheless he showed weakness in certain directions. He frequently made mistakes in his estimate of men, more particularly in the military leaders with whom from time to time he allied himself. He failed clearly to see the danger of seeking his own high ends through methods which were really at variance with them. He was not able to see all round a question and therefore lacked powers of constructive statesmanship. His was a restless spirit and he was not content to settle down to more commonplace tasks. The most considerable effort made by

Dr. Sun in the field of constructive policy is to be found in his volume *The International Development of China* (1922).

His public works include a number of speeches, articles and pamphlets, more particularly the following: *The Doctrine of Sun Wen*; *The International Development of China*; *The Principles of Democratic Government* (statement of 25 outstanding points). See Sir James Cantlie and C. S. Jones, *Sun Yat Sen and the Awakening of China* (1912); P. Linebarger, *Sun Yat Sen and the Chinese Republic* (1925). (H. T. H.)

**SUPER-POWER.**—This phrase has come into wide use in connection with the extensive development of the electric power industry. It has been defined as "the systematic grouping and interconnection of existing power systems to the end that greater economy will be effected." According to another authority, "Super-power is the term used to designate the furnishing of large blocks of power generated in efficient power stations and transmitted in bulk at very high voltage, such as 220,000, and supplied through transformers to the present power systems for distribution at some lower voltage." An interesting analogy compares a super-power system to a power bank in which deposits or withdrawals are made at widely different points. Any surplus production of an existing power system can be absorbed and simultaneously a deficit on the part of another system can be made up by the resources of the super-power network.

**Basis of the System.**—In its strictly technical sense, as pointed out by W. S. Murray, the basis for a super-power system lies in the economy effected by the interconnection of electric power systems whose peak loads are reached at different times; in other words diversity economy. In a power system, A, the capacity of plant in the power station must at least be equal to the peak or maximum load although the average load may be

FIG. 1.—Map of the region included in the U.S. super-power survey, 1920. (Transactions A.I.E.E. 1920.)

only from 20% to 30% of this. A neighbouring power company, B, may have similar characteristics except that the time when the maximum load occurs may be quite different from that of A. In such a case it is obvious that, given suitable connections, power house A could carry the peak load on both systems. This would leave power house B with a non-peak or base load which might be carried most economically by a hydroelectric plant or a steam plant located at the coal mine but within the range of practical transmission. The extension of this idea to the operation of a number of independent systems is the basis of super-power. The most important of the advantages are:—

- (a) A higher capacity factor on the combined systems resulting in fewer generating units and reduced investment per kilowatt.
- (b) A higher load factor resulting in substantial fuel economy.
- (c) Greater reliability and continuity of service, especially in the supply of large railway or industrial loads.

**U.S. Government Survey.**—In the years 1919-20 a Government super-power survey was made in the United States cover-

These three groups of generating stations are to be connected by transmission lines direct to the 220,000 volt bus line at the most logical points. Base load stations are mentioned particularly because it is assumed that the peak loads would be carried by the most economical of the existing stations in the local industrial centres. It is clear, however, that, with the development of the super-power idea, and the improvement in load- and capacity-factor, local peak loads would become of less and less importance. While the centres of population form the logical foci for factories, it is not necessary nor desirable for large power stations to be built in the heart of modern industrial cities and one effect of super-power will probably be the decentralisation of the power industry, the principal power sources being at the mine and the waterfall with auxiliary stations a short distance outside the individual centres.

FIG. 2.—Main transmission lines and location of base load power plants for the U.S. super-power survey, 1920.

ing the region lying between Boston and Washington with a view to ascertaining what fuel economies and other advantages might be derived from interconnection and co-ordination of the power sources and industries in this territory. The subsequent report, in the preparation of which a large body of representative engineers co-operated, affords an admirable model for any study of this kind. It was shown that the total capacity of all the individual generating plants in the region was then about 13,000,000 kw. but the average load factor was only 15%. In other words, for every 100 kw. of generator capacity only an average of 15 kw. was produced. By reinforcing the power utilities with a super-power system it was shown that the load factor could be raised to 50 or 60%, and that coal could be saved to the extent of 30,000,000 tons per year. Many contingent economies were indicated, such as the reduced load on the railways for coal transportation and the diminished maintenance and upkeep of machinery.

While the report made clear that it is no function of the super-power system to replace the existing power companies, it was also shown that something more than the mere linking up of the present networks would be called for in order to meet the expanding demand for electric power. The following were therefore proposed to amplify the existing equipment of the individual power companies.

- (a) A transmission bus line extending the entire length of the super-power region from Boston to Washington consisting of four circuits at 220,000 volts.
- (b) A group of base load power stations located in the bituminous coal-fields of West Virginia.
- (c) A similar group located in the anthracite coal-fields of Pennsylvania.
- (d) A hydroelectric power plant on the St. Lawrence river.

FIG. 3.—Super-power system of the New England Power Co. (Map divided into 25 mile squares.)

**Other Systems.**—While the development of electric power in the Boston-Washington zone has not entirely followed the lines of the above report, the tendency is in that direction. Meantime other super-power systems have grown up—mainly in the United States, of which the New England Power System and its affiliations form an interesting example (fig. 3). This company operating in Massachusetts, Vermont, New Hampshire, Connecticut and Rhode Island covers a territory of more than 20,000 sq. m. with connections to systems in other states. It has been evolved by the consolidation both financially and physically of a number of smaller independent power companies and operates (1926) eight water-power and six steam-power stations. It has a total installed capacity of nearly 200,000 kw. and in addition purchases 100,000 kw. from neighbouring systems. It should be noted that this does not comprise the entire energy consumption of the territory because several large steam plants of modern design are independently operated in Boston, Providence and other large cities. These are, however, susceptible of being connected with the New England system. Transmission lines amount to a total of 765 m. of 110,000 and 66,000 volts. A glance at the map will show widely distributed load centres concentrating toward the southeast extremity of the region and supplied by steam stations in the proximate locality. About 100 m. to the west is the Deerfield river, on which a number of power houses have been built, chief among which is that at Davis Bridge (45,000 kw.), from which an important trunk line has been constructed 76 m. southeast to the substation at Milbury.

This line, which will ultimately be operated at 220,000 volts, forms the backbone of the system and serves as a bus to distribute the load between the hydroelectric stations in the west, the steam stations in the east and the various load centres.

While special attention has been drawn to the New England system, this has been used simply as an illustration. The American Gas and Electric Co. in western Pennsylvania and the Southern Power Co. in North Carolina and a number of others might have been described as exemplifying the super-power idea in practice.

*Developments in Japan.*—Outside the United States, Japan and Germany have shown the most important developments. In central Japan there is virtually no coal and, while water-power sites are plentiful and are freely developed, the variation in flow of the streams is a serious handicap and leads to a high cost of development because of the difficulty of storage as well as a low capacity factor. This has been fully recognised by the engineers of some of the most important power systems. In a study of the subject Minoru Fukuda has shown that the present energy demand of central Japan is of the order of 1,400,000 kw. divided almost equally between the eastern and western zones. The potential water power available is 3,530,000 kw. but the dry season reduces this by 20%. To utilise the water power economically therefore an auxiliary 700,000 kw. must be provided by steam plants to operate during the low-water period. While there appears to be a reasonable surplus of potential power over consumed power, the load- and diversity-factors must be taken into account and only by the adoption of super-power principles can these power resources be made to meet the demand which will come upon the combined systems.

*Conditions in Germany.*—In Germany the problem has been somewhat different and less onerous because the majority of the new power plants are designed to burn briquetted lignite; the plants have been built in close proximity to the mines and, because of the relative absence of water power, the problems of distributing base and peak loads between steam and water stations have not arisen. Nevertheless the super-power idea is well illustrated by recent developments of the Elektrowerke A. G. and the Rhenische Westfälische Elektrizitätswerk.

**BIBLIOGRAPHY.**—The literature of super-power is distributed through the transactions of the principal national engineering societies during the years 1919-26, particularly the *Transactions of the American Institute of Electrical Engineers* (New York) and *Trans. World Power Conference 1924* (London, 1925); *Professional Paper No. 123*, issued by the U. S. Geological Survey, describes most fully the super-power survey of the Boston-Washington region already referred to, as well as treating of the general principles of the subject. In addition should be mentioned W. S. Murray, *Superpower* (1925); G. Klingenberg, *Bau Grosser Elektrizitätswerke* (1913 and 1914). (E. V. P.)

**SUPILO, FRANO** (1870-1917), Yugoslav statesman, was born of poor Croat parents at Cavtat (Ragusa Vecchia) in southern Dalmatia. At the age of 20 he obtained a subordinate post on the staff of a small provincial Croat newspaper. In 1900 he was made the editor of *Novi List*, a new paper, founded by a group of Croat patriots at Fiume, and he rapidly made this a rallying ground for the younger generation of Yugoslavs in their struggle against the intolerable régime of Count Khuen Héderváry. In 1905, together with Trumbić, Čingrija and Smolaka, he played a leading part in drawing up the resolution of Fiume, which became the basis of political co-operation between Serbs and Croats in the critical period before the World War. When the Magyar Coalition parties came into power in Hungary in April 1906 and placed the Serbo-Croat coalition in office at Zagreb, Supilo became a deputy at Budapest.

Within a year Magyarising tendencies produced an acute conflict between Budapest and Zagreb, and for a time Supilo was the soul of Croat resistance. He thus became a marked man and was specially aimed at in the notorious forgeries by which the Austro-Hungarian Foreign Office attempted to prove Serbia's revolutionary intrigues in Croatia and thereby to justify the annexation of Bosnia in 1908. At the Friedjung trial, however, in Dec. 1909 Supilo was triumphantly vindicated.

On the eve of the World War he devoted his energies to pleading the cause of Yugoslav unity before the statesmen of the Entente. He was the first to discover the secret negotiations with Italy which culminated in the Treaty of London (April 26 1915) and earnestly warned Sazonov of the disastrous complications to which it would give rise; but he was unable to prevent the promise of wide Slav territories on the Eastern Adriatic to Italy in the event of victory. Supilo came into conflict with the Pan-Serb and reactionary tendencies of Pašić, and even withdrew from the Yugoslav Committee, which in the early stages of the War he regarded as unduly subservient to Belgrade. But before his premature death (in London, Sept. 23 1917) he heartily endorsed the Declaration of Corfu, issued in July 1917, which laid down the broad lines upon which the future Yugoslav State was to be constructed.

**SUPPLY AND TRANSPORT** (see 26.113).—The administration of supply and transport became of the first importance as the World War developed into a struggle between two groups of nations, each using the full resources of civilisation to exhaust the other. In the last stage, supply was the determining factor; munitions, food, equipment, railways, roads, ships, had become the most important things, and victory inclined to the force which could best maintain supplies, as well as men, at some particular point; which could best develop, conserve and transport its material. At the same time, in foodstuffs, forage, clothing, timber and metals, and in transport material, the world shortage was acute. Thus the work of administration was not only very heavy because of the number of combatants and the development in scale of equipment, but also because of the economic scarcity owing to world exhaustion.

The development of supply and transport services will be best understood by a very brief review of the positions respectively of the chief armies at the beginning and end of the World War.

*Position in 1914.*—When the armies first took the field in 1914, Germany was at a clear advantage. She had prepared for the War with meticulous care. The equipment of the German soldier was in every detail complete, and comprised several novel ideas for greater comfort and efficiency. The German transport organisation was fine, and showed that there had been a clear thinking out in advance of the new problems of ammunition supply raised by the free use of heavy artillery in the field. German staff documents published since the War by General Ludendorff indicate that these matters had been closely studied from 1910 onwards, and that the German staff were very confident of the superiority of their organisation of transport and supply. The French administrative services in 1914 appeared much weaker if examination were confined to plans and matériel. The troops were not as well provided for, the transport organisation not as well planned. But if the human factor were taken into consideration, much of the handicap was made up. The French showed a genius for improvisation on the actual battle field and a faculty for "getting there" with inferior means. Their food scales for man and beast (to give an example) spelt scarcity in British eyes; but they sufficed. In the battle the French soldier was not inferior in energy and endurance and the French transport was generally up to time.

*British Services in 1914.*—The British administrative services in 1914 were lavish both of supplies and transport. But the British Force was small, and though its scale of transport was generous compared with the French, the total was only 250 motor-cars, 950 motor-lorries, and 40,000 horses. With railway transport it had at first no concern, as the French took charge of that.

*Progress During the War.*—As the War developed, the Germans suffered from a steady deterioration as compared with the French and the British. The War had become a contest of matériel, in which Germany could not keep up. The French, on the other hand, were able to develop their supply and transport on more generous lines with the help of British and American resources. The British developed a complete machine of administration, helped by the fact that the nation took the view that all reasonable expenditure was justified in securing for the troops the best

possible chance of victory and the best possible comfort in the trenches. But the Germans, considering the depletion of their resources, kept up a wonderful efficiency in supply and transport. They realised, perhaps more clearly than the other armies, the importance of these services; in their High Command, the Quartermaster-General was allowed a remarkable power.

*Trench Warfare Conditions.*—During the long period of "trench warfare" which followed the battle of the Marne, the administrative systems of the three armies were adapted to new conditions, the chief of which were: an enormous increase of ammunition expenditure; the introduction of poison gas as a weapon, calling for new supplies of offensive and defensive material; and a great simplification of transport which in a stabilised warfare could follow almost a civilian routine disturbed only by the chances of shell fire and aerial bombs.

Administration thus, whilst it had to cope with the progressive increase in the scale and variety of supplies per division, was given as a rule ample time to increase its transport facilities. It could add to its broad-gauge railway tracks, supplement them by light railways and tramways as well as by motor roads and develop the canal systems as useful adjuncts. As the War opened out, with the development of great attacks on both sides, problems of supply and transport became more difficult. In facing such a German effort as the Verdun attacks of 1916, the French had a very difficult problem of transport, which was met by a motor-lorry mobilisation, the success of which was one of the great feats of the War.

*Reorganisation of British System.*—From 1914 up to the date of the first battle of the Somme (July 1916) the British administrative services had had no very severe test, but had developed their system almost completely. In munitions, the British Army was now better supplied than any other force in the field. It had control of its own railway services and supplementing the French broad-gauge railway system on its front—which it had taken over and increased—had a system of light railways, and a greatly increased scale of motor transport. But the Somme battle showed that supply had been increased beyond the scale that transport could cope with. There followed in Nov. 1916 a reorganisation of the system. One feature of this reorganisation was good. The division of authority which put the administrative services really under two heads, one for the battle area and one for lines of communication, was done away with. The military railways, which had been hitherto somewhat starved, were reorganised according to the plans of a civilian expert and were generously supplied with staff and material. But here, what proved in the result to be a mistake in organisation was made: railways were separated from the control of the quartermaster-general (who kept control of other forms of transport) and put under a director-general of transportation. Thus there were two separate transport authorities.

*Errors of Dual Control.*—After the battle of the Somme the line was practically stable for a long time. Whilst this almost stationary trench warfare continued, the weakness of the division of authority and the mistake of allowing any but the military idea to rule in an essential part of an army organisation were not apparent. When the Germans attacked in the spring of 1918 the mistake showed very clearly, and the railways were brought again under the control of the quartermaster-general, after an interval during which the traffic to be carried and its priority was regulated by a committee composed of staff officers and officers of the transportation directorate. But the transport situation in the interval was very critical. The German advance had brought the British front lateral line—St. Just—Amiens—St. Pol—Hazebrouck, under shell fire at many points. The Germans, whose strategy under General Ludendorff was dominated largely by transport considerations, sought to paralyse completely the whole railway system by continuous air attack on the British rear lateral—Eu—Abbeville—Étaples, especially at the points where it crossed the rivers Canche and Somme. Whole-hearted work in building "avoiding" lines and bridges and the efforts of the motor transport just kept the position in hand until a British advance in front of Amiens relieved the

front lateral. Fortunately the building up of a G.H.Q. reserve of motor lorries had just been brought to completion.

*Motor Transport System.*—In the winter of 1917-8 the battle of Passchendaele had exposed a weakness in light railways—that they had to work along defined tracks which could be intensively shelled by the enemy—and therefore it was decided to trust more to motor transport. There was effected a complete reorganisation of it with the central idea of doing away as far as possible with the "earmarking" of motor vehicles for particular units or particular tasks and making its total strength completely mobile and liquid. Vehicles saved by this "pooling" were formed into a G.H.Q. motor reserve. In the spring of 1918 this G.H.Q. motor reserve was able to take up part of the traffic load and was largely responsible for saving the situation. (See MOTOR TRANSPORT.)

*Transport Values.*—One of the most interesting problems of supply and transport is that of the relative value of roads (motor and horse traction), light railways and broad-gauge railways. Light railways (*q.v.*) at one stage of the War were perhaps overestimated. There was an inclination to regard them as all-sufficing. The British system ultimately gave to them what was considered their proper rôle, recognising that they were most valuable when the line of battle was stabilised for some length of time, but tended to be less valuable as the war became one of movement. In the spring of 1918 the British Army had 920 m. of light railways in operation: in the summer, 100 m. less. Its advance was planned on the principle of concentrating labour in pushing forward the broad-gauge railways and then the roads from them, trusting to motor transport and to horse transport to carry on the load from broad-gauge railroad. Earlier in 1918, controversy on the subject was keen and the French were inclined to take a differing view. The Germans were tied to light railways, for they had not the means to extend their motor traction. The position on Nov. 11 1918 seemed to justify the British view. From a transport point of view the British force was at that date in the best position of all the Allies to make a further advance.

*Position in 1918.*—The autumn of 1918 will be the most useful date to compare the administrative machines of the Allied armies. Both French and American systems kept a dividing line as regards administration between base and the fighting line. The British system had abolished that in 1916 (with the post of inspector-general lines of communication). The French divided the zone of the armies into the zone of the advance and the zone of supplies (with sometimes an intermediate zone). In the zone of the advance, administration was in charge of the *aide major-général chargé de la direction de l'arrière* at headquarters. But his administration had no functions of procurement, only of distribution. In some points of administration the dividing line between the zone of advance and the zone of supplies was abolished, *e.g.*, all motor transport and all light railways, wherever operating, were controlled from headquarters. The French system of supply and distribution was fashioned for war in the home country or near to it; when it was transplanted (for instance to Salonika) it was adapted nearer to the British system. The American system put administration on the fighting line under an assistant chief of staff (G.4) at G.H.Q., and on lines of communication under a general commanding service of supply (corresponding in some degree to the old British Inspector-General of Communications). Under the American system the chiefs of the supply service were not at G.H.Q. but at the H.Q. of service of supply.

With both the French and the American systems, evacuation and hospitalisation of casualties were purely "Q" services; in the British Army they were under the Adjutant-General, assisted by the Quartermaster-General. Some other differences came from geographical reasons. The Americans had to have their real supply base in France (for the British, the United Kingdom, and for the French, France was the ultimate supply base); so they held great stocks in depots, 15 days of supplies in advance depots, 30 days of supplies in intermediate depots, 45 days of supplies in base depots. The American Army relied more largely on local

purchases (from the Allied armies and from European civilian sources) than did the armies with their home bases nearer at hand. General Pershing founded a general purchasing agency to control these purchases. In 1916, of 17,600,000 ship tons used by the American Army, only 7,600,000 tons came from the U.S.A. and 10,000,000 tons were purchased locally, and to the end of the campaign the American Army drew largely upon British and French supplies.

*Relations with Navy.*—The British administrative machine in one point was inferior to the American machine in 1918. Under the British system the navy had control of all supplies by ship until discharged from the transport. The navy could put a supply ship into any port it pleased and naturally was mainly guided by shipping considerations. The American system put the supply ships under army direction when they came within the three-mile limit from shore, and shipping could then be directed to the port of supply which was most convenient from the army point of view. The French and the Americans used the railway regulating stations as depots, the British used them as sorting stations only. The British used the base ports to sort goods to a great extent; the Americans did not do so. In the autumn of 1918 they found their one great depot and sorting and regulating station at Is-sur-Tille insufficient for the needs of their growing army and they were proceeding with the organisation of another station when the Armistice came.

The staffs of the various combatant nations are working out the lessons of administration as taught by the World War. One principle seems to be generally accepted, that it is wise to centralise all administration of supplies and transport under one head over the whole war area, trusting to him to devolve and co-ordinate. Another conclusion is that if civilisation has ever to face another great war it will be, even more than the contest of 1914–8, a war of material, a struggle in which supply and transport will be the governing factors. (I. C.)

**SUPREME COUNCIL.**—This term was evolved to denote the organ of supreme control at the Peace Conference at Paris in 1919. It was thought by some (and the idea was subsequently expressed by Sir Maurice Hankey, the Secretary to the Council of Four at Paris) that this device was a new one, and the phrase "Diplomacy by Conference" was coined to express it. But, in fact, a similar procedure was followed at Vienna during 1814–5 and subsequent years, with strikingly analogous results.

Lord Castlereagh devised the system in the autumn of 1814 of discussing large questions of policy with the plenipotentiaries of the other Great Powers—Austria, Prussia and Russia. These meetings were of the nature of conversations and were quite informal, but were generally responsible for the decisions that were taken. In Jan. 1815 Talleyrand, the representative of France, was admitted as a fifth member to the inner Cabinet of Four. Castlereagh was so pleased with this system that he endeavoured to prolong it by arranging for "periodic reunions" of the Great Powers (Article VI. of the Second Treaty of Paris, 1815). These reunions resulted in Congresses and were, for a time, successful in settling the affairs of Europe. But from 1818 onwards difficulties began to appear. Castlereagh insisted that the British representative at the Congress of Troppau (1820) and of Laibach (1821) should be merely a spectator. At Verona (1822), Canning, who had succeeded Castlereagh as British Foreign Minister, instructed the British representative to dissent from the proceedings, and this action, in effect, ended the system of "periodic reunions" which had obtained between 1814 and 1822. The experiments between the years 1919–22 followed an almost exactly similar course.

*The Peace Conference.*—The Peace Conference which opened at Paris in Jan. 1919 started by excluding all but the Great Powers from anything but formal deliberations. The original supreme organ was known as "The Council of Ten" and consisted of the heads of the Delegations of the Great Powers and of their respective Foreign Secretaries. This body was found too unwieldy, and it was considered that its numbers caused leakage and undue publicity. To meet this difficulty President Wilson proposed, and Mr. Lloyd George supported, the experi-

ment of a Council of Four ("The Big Four"), who were the above named, together with M. Clemenceau (France) and Signor Orlando (Italy).<sup>1</sup> By this device business was transacted rapidly and informally and secrecy effectively preserved. After the departure of President Wilson and Mr. Lloyd George on June 28 1919, the Council of Four was superseded by a Council of Five which included Japan. The leading diplomat of each Great Power attended on behalf of his country. This arrangement ended in Jan. 1920, and the United States then withdrew her representative altogether.

The Supreme Council (as it was now called) did not, however, die at once, though it ceased to sit at Paris *en permanence*. Parts of its functions were transferred to the Ambassadors' Conference (*q.v.*) and part to the League of Nations (*q.v.*). Attempts were, however, still made to establish a system of "periodic reunions" between the premiers or leading men representing each Great Power. This was exactly on the lines previously attempted by Lord Castlereagh, but the meetings were actually much more frequent. There were nine such in 1920, of which three were in England; six in 1921, of which three were in England; two in 1922, of which none were in England.

The "periodic reunions" of the Castlereagh era were successful until the then enemy (France) had paid a considerable part of her indemnity, that is, up till 1818. After that date divergences between the Great Powers began to appear. So also during the years 1919–21. At the Conference of London (Feb. 21–March 14 1921) it became quite clear to the Great Powers that Germany had, in the military sense, become incapable of resisting them. It was also doubtful whether any forcible measures could actually produce substantial sums by way of reparation. On this point, grave divergences appeared between England and France. The supreme test came at the Conference of Paris (Aug. 8–13 1921). At that meeting there was a complete division between the French and British views over the assignment of territory in Silesia respectively to Germany and to Poland as a result of plebiscite. Finding agreement impossible Mr. Lloyd George appealed to the League of Nations to settle the Silesian boundary, and M. Briand agreed to accept the award of the League on behalf of France.

Mr. Lloyd George's appeal showed quite clearly that the Supreme Council was no longer a body able to settle disputes between its members, in spite of the informal and unofficial character of its proceedings and of the close personal intimacy between its members. None the less two further meetings took place. That at Cannes (Jan. 6–13 1922) failed because M. Briand was overthrown by the majority in the French Parliament, while the Council was actually sitting (Jan. 12). A desperate effort by Mr. Lloyd George to retrieve the situation by summoning a new Council at Genoa (April 10–May 19 1922) failed because of French hostility to the proceedings.

The failure of the Supreme Council would appear to have been inherent in the very circumstances of its origin and constitution. Like the similar organism created by Castlereagh, it was evolved to meet a certain need, and decayed when that need ceased to be imperative. It was necessary at Vienna in 1814 and at Paris in 1919 to devise some method by which the work of the Peace Conference could be rapidly thrown into shape and decided without too many plenipotentiaries encumbering the discussion and too much outside pressure embarrassing the decision. During periods of stress of this kind, moreover, diplomats are much more ready to arrive at agreement than during periods of comparative peace. Hence so soon as the fear of the armed enemy disappeared, divergences began to appear among the Allies. This was the case in 1818 and again in 1921. The fact is that "Diplomacy by Conference" is a method, a system or a means for oiling the wheels and for easing the pressure. But it cannot, of itself, remove pressure or create harmony.

The history of the Supreme Council, alike in 1815 and 1919, shows that to eschew formalities and to decide great issues in

<sup>1</sup> The Japanese occasionally sent a representative when their interests were involved, thus making a fifth member.

secret is a good method for transacting the business of a Peace Conference. It is not, and cannot be, a permanent system for conducting the affairs of the world.

**SURGERY.** (*see* 27, 125).—In the art of surgery, almost every problem is relative. Surgical indications depend on many factors, the patient's age and general condition, and the presence of diseases other than that for which surgical relief is sought. It requires knowledge, judgment based upon experience, and sound common sense to reach a proper decision. There are exceptions to almost every rule and therefore, in the space allotted to this article, it will be impossible to qualify all statements as fully as in strictly professional writings. An endeavour will be made to furnish the lay reader with a brief summary of the present status and outstanding advances of modern surgery, both general and regional.

Since 1910 the physiological trend of thought has led to great improvements in diagnosis. The X-ray and tests in conjunction with it are perhaps the most outstanding examples. Operable conditions are determined earlier and with greater accuracy. Operations are conducted with correspondingly greater safety, lower mortality and proportionately better end-results. In other words the earlier that operation is undertaken in the course of a disease requiring surgical intervention, the safer for the patient; complications are less likely and the prospects of complete restoration to health more probable. Quite opposite is the case of those reaching the surgeon far advanced in their disease, but even for them much can be done. A measure such as transfusion (*see* TRANSFUSION OF BLOOD) prior to operation, may furnish just sufficient vitality to tide the sufferer over a brief but lifesaving operation. In the operating room the improved modern forms of local and general anaesthesia may be used in combination most appropriate to each particular case. Visibility in the field of operation has been greatly improved by better lighting, better retraction of tissues and the employment of suction apparatus for removal of obscuring fluids such as pus, blood and bile.

To lessen surgical risk certain operations may be divided into several stages, each stage being performed as the patient's condition permits. Once the operation is passed, a host of measures are available for sustaining life and increasing comfort. Notable examples among these are the semi-reclining position similar to that assumed in a steamer chair, various methods of administering fluids other than by mouth, transfusion where much blood has been lost and lastly the use of insulin combined with glucose for those having diabetes. Competent, intelligent nursing cannot be left out of this list. As convalescence goes on, physiotherapeutic measures, the value of which came into such prominence during and after the World War, are employed to hasten recovery and accelerate restoration of function. The intelligent lay public has come to appreciate the importance of early surgical intervention, an indispensable factor in the success of present-day surgery.

**The X-Ray in Relation to Surgical Diagnosis.**—Often the results of an X-ray examination can be given their correct diagnostic value only when taken in consideration with the history, physical signs and perhaps certain laboratory tests. (*See* DIAGNOSIS.) As a consequence of co-operation between various specialists, *e.g.*, the surgeon, the physician, the pathologist and the Röntgenologist, one sees refinements and advances in diagnosis, not attainable in the pre-Röntgen era. Operable conditions are recognised much earlier, and the patient often saved months of suffering. Unnecessary operations are avoided for those the X-ray shows to be beyond the aid of surgical treatment. Lastly,

the ubiquitous functional neurotic whose symptoms so closely simulate organic disease is saved a needless operation, and is referred to the neurologist or psychiatrist for the rational care of his disabling condition. Furthermore, information obtained by the Röntgen ray is of the utmost value as a control in the course of surgical treatment and in estimation of end-results.

Exposures are taken from in front (antero-posteriorly) and from the side (laterally) whenever feasible, particularly in fractures. Stereoscopic views are especially valuable for depicting finer details in regions of the skull, thorax and pelvis; and also for more exact location of foreign bodies such as needles and bullets. (*See* RÖNTGENOLOGY.) The diagnostic and therapeutic uses of the X-ray are entirely different in matters of wavelength, duration of exposure and so forth. Photographic glass plates have been entirely supplanted by celluloid films, because of the obvious physical advantages of the films in being lighter, less bulky and non-breakable. To avoid repetition, special applications of the X-ray and other modern diagnostic methods will be mentioned as occasion requires in the next to follow.

**Surgical Aspect of Tuberculosis.**—In 1910 the curative value of rest and hygienic measures was well recognised in the treatment of this disease. Rest of the affected part as well as of the entire body was practised then. Tuberculosis of bones and joints was treated by long immobilisation in plaster-of-Paris casts, braces and so forth. Ankylosis (a stiff joint) in the most favourable (that is, the least disadvantageous) position was the goal sought at that time as it still is in far-gone cases. Nowadays in early stages, the Rollier method of heliotherapy has furnished a great advance. Casts holding the affected joint at rest have openings cut in them to permit exposure of the diseased area to direct sunlight. Furthermore, the treatment consists of gradually increasing the time of exposure and area exposed until the entire body except the head is accustomed to sunlight for long periods of time. This results not only in great improvement in general health but a regression of the local tubercular process with ultimate return of function. Essential factors of the Rollier method are: high altitude (about double the number of actinic rays are available at 5,000 to 7,000 ft. than at sea level) and sunlight without wind. The sanatoria lie in a high, sheltered Alpine valley where sunshine is very prevalent.

The sunlight treatment has also proved a most efficient means of curing other forms of so-called surgical tuberculosis; for example, tuberculous glands of the neck (tuberculous cervical lymph adenitis) in all stages. Nowadays it must be mentioned that this condition is far less common in the United States than formerly, owing to the great regression of tuberculosis in general and to the widely practised removal of diseased tonsils and adenoids in infants and children, the tonsil being the port of entry for the tubercle bacillus (tonsils removed from patients with tuberculous glands of the neck almost invariably show lesions of tuberculosis upon microscopical examination). Artificial sunlight in those countries where sunlight is infrequent has proven of great value. It must be emphasised that the improvement in the general health following exposure of the entire body is just as essential to cure as local exposure of the affected region. (*See* also HELIOTHERAPY.)

Another regional application of the principle that rest hastens healing in tuberculosis is the employment of artificial pneumothorax which allows collapse and inactivity of one lung by filling the pleural cavity of that side with nitrogen gas. Where this is not feasible because of pleural adhesions, a plastic operation (extrapleural thoracoplasty) accomplishes the desired purpose by diminishing the size of bony thorax.

**Surgical Aspect of Syphilis.**—Examination of the blood for the Wassermann reaction is a routine in every well organised hospital and clinic. When positive in an individual without obviously characteristic lesions, it generally indicates latent but actively existent syphilis. Such knowledge is of the greatest

<sup>1</sup> Certain diseases like active malaria and leprosy also produce a positive Wassermann reaction. Sometimes the reaction is also seen during an acute febrile disease and for a day or so after administration of a general anaesthetic.

value. The late manifestations of syphilis often simulate cancer or tuberculosis, and while the presence of syphilis does not exclude either of these other diseases, further diagnostic measures and anti-syphilitic treatment are invariably indicated before operation is resorted to. X-ray pictures of bones affected by syphilis show characteristics quite different from the lesions of tuberculosis or cancer in osseous tissue. If after several weeks of anti-syphilitic treatment there is no apparent improvement, it is then time to consider surgical intervention.

In surgical emergencies such as strangulated hernia, perforated gastric ulcer or acute appendicitis, operation cannot be deferred, but in the presence of florid syphilis with obvious and active lesions, the greatest care must be exercised by surgeons and attendants to protect themselves against accidental wounds or inadvertent contacts. The mysterious failure to heal, noted in certain clean postoperative wounds in years gone by, is now largely explained by a positive Wassermann reaction in an apparently healthy patient. Other causes for the failure of clean wounds to unite also exist, but one must exclude syphilis before considering these. Long-standing syphilitic lesions of the oral cavity are not infrequently followed by a cancer in old scar tissues, so that one must be on the lookout for this concurrent incidence, the failure to recognise which has often led to diagnosis so late that surgical relief for the cancer was impossible and death almost inevitably followed.

**Cancer.**—Cancer often begins as a painless, hard, slowly growing lump. At first it remains localised, then as time goes on it spreads to the regional lymphatics (for example, cancer of the breast spreads to the lymph-nodes of the armpit) and finally it is found in distant parts of the body far removed from its original site. The surgical treatment consists in wide excision of the tissues around a primary cancer together with removal of the regional lymphatics. To use the same example, in cancer of the breast the lymphatics of the axilla are dissected out in one mass together with the affected breast. Likewise in cancer of the tongue, lips or cheek, the lymphatics of the neck are removed en bloc in addition to wide removal of tissues around the original focus of growth (see CANCER RESEARCH). If there is no recurrence within five years after removal, a cure is probable; most recurrences come on within three years; after five years they become less and less frequent.

Except for the treatment of a relatively benign type of facial cancer (basal cell carcinoma), radium is better reserved for the palliative treatment of inoperable cancer at least at the present writing. Radium is ineffective farther than 1 cm. from the point of application. X-rays are used with far more accurate control of therapeutic dosage both for preoperative and postoperative irradiation, and for the palliative treatment of inoperable cancers. Periodic physical examination at least once a year is the best means of safe-guarding the public, as early discovery and early removal offer the best hope of total eradication.

**Surgical Aspect of Typhoid Fever.**—Since the era of preventive inoculation typhoid fever is no longer the menace it once was. Nowadays surgeons rarely see its surgical complications of hemorrhage from the bowel, perforation of the small intestine and metastatic typhoid abscesses. (See TYPHOID FEVER.)

**Tetanus or Lockjaw.**—Tetanus is another disease one rarely sees now, thanks to routine injection of tetanus antitoxin in the presence of accidental wounds. Comparison of the medical reports on the incidence of tetanus in the World War with similar reports prior to the introduction of routine prophylactic injection will demonstrate the protection we now enjoy.

**Gas Bacillus Infection.**—Gas gangrene, as this is usually called, is characterised by rapid spread in the tissues, their typical brawny look and the tell-tale subcutaneous crackle felt by the examining fingers. Ruthless removal (including even amputation) of all diseased tissue and administration of a specially prepared serum must be carried out as soon as the diagnosis is made if life is to be saved. These cases were all too frequently seen in the World War; fortunately they are less common in civil life.

**Surgical Aspect of Diabetes.**—Operative treatment in the presence of diabetes is practically the same as in patients without this disease, except for the increased risk. The preoperative administration of insulin and glucose for the prevention of postoperative acidosis is a well recognised procedure. Prolonged anti-diabetic treatment before operation for conditions such as diabetic gangrene, carbuncle and acute appendicitis has not met with success. The patients have not improved as was hoped and the postponement of the operation has resulted in their being in poorer condition to stand it than if surgical measures had been taken more promptly. While it is true that insulin is a specific for diabetic coma, one often sees comatose diabetics who fail to react to insulin; the explanation of this is that the coma is of uraemic origin or, plainly put, the diseased kidneys have ceased to function adequately. (See also DIABETES; INSULIN.)

**Preventive Medicine.**—Present-day medicine and surgery are preventive in character. Nowhere is this better illustrated than in the modern care of children and infants. By timely and relatively simple methods, conditions causing deformity or systemic disease are checked in their incipency; for example, infantile scurvy and rickets are rarely seen nowadays, and, if present, can be cured by simple dietetic and hygienic measures. Operations for rachitic deformities such as bow-legs are much rarer than in former years. The removal of diseased tonsils and adenoids has greatly diminished the incidence of quinsy, otitis media (inflammation of the middle ear), mastoiditis, acute articular rheumatism, endocarditis and tuberculous glands of the neck. Modern dentistry also has its share in preventing deformity and eliminating focal infection, in children as well as in adults. (See DENTISTRY.) The earlier recognition of such diseases as empyema of the thorax following pneumonia, foreign bodies in the bronchial tree (see BRONCHOSCOPY below), intussusception (a form of acute intestinal obstruction especially prevalent in infancy) and acute appendicitis, has greatly reduced the mortality of childhood from these causes.

Hare-lip and cleft palate are congenital deformities which often occur together. The hare-lip should be repaired, under local anaesthesia within a few weeks after birth. This union of the lip causes the gap in the cleft palate to narrow as time goes on, facilitating surgical closure later. Even though the operative repair of cleft palates be successful, speech defects often remain in spite of training to overcome them.

Congenital pyloric stenosis (a narrowing of the lower or pyloric end of the stomach by muscular overgrowth of the pyloric sphincter) was formerly relieved by the operation of gastro-enterostomy, i.e., anastomosing stomach with small intestine. This was designed to prevent death from inanition through failure of food to leave the stomach. More recently, the operation devised by Rammstedt, which consists in dividing this muscular constriction longitudinally down in the lining mucous membrane of the stomach, has effectively relieved constriction. The procedure is much shorter and may readily be performed under local anaesthesia upon the new-born; the mortality has been greatly decreased.

**Transplantation of Tissue.**—Transplantation of tissues is, on the whole, unsatisfactory except when taken from the same individual. The transplants when taken from others, even from blood relatives, may at first heal into place but ultimately disappear, leaving scar tissue behind. Taken from the same individual, the less highly organised tissue such as skin, fat, fascia, tendon, cartilage and bone are amenable to successful transplantation from one region to another. Skin transplantation is an old, well recognised procedure which has undergone considerable refinement of late years. For description of its manifold uses and many ingenious variations of technique now successfully employed, the reader is referred to standard works on plastic and cosmetic surgery. Indications for transplantation and choice of other tissues, the most suitable types of procedure, after-care and the criteria of success are so relative and manifold that space is lacking for adequate discussion. By no means has the last word been said upon this subject. (See also BURNS.)

## SURGICAL ANAESTHESIA

*General Anaesthesia* (see also ANAESTHETICS).—Chloroform is practically obsolete, being used only upon the rarest occasions and then by skilled professional anaesthetists. In less experienced hands it has proved to be highly dangerous. Compared with ether, chloroform would represent the sharpest kind of a razor, while ether might represent a relatively harmless butter-knife. In obstetrics chloroform has likewise been supplanted by ether or nitrous oxide and oxygen because it has been proved that chloroform is harmful to the liver. Late chloroform poisoning coming on ten days after its administration is identical with hydrochloric acid poisoning. In eclampsia the liver cells are already greatly damaged and chloroform adds insult to injury. The deaths from eclampsia have greatly diminished since ether has been used to control the convulsions. Ethyl chloride may be called a highly volatile chloroform. It is extremely dangerous because of the ease with which an overdose may inadvertently be administered.

Until 1915 ether was the anaesthetic of choice, but since then nitrous oxide with oxygen has come into deserved popularity; with it ether is used in minimal amounts to afford greater muscular relaxation for a short period whenever this may be required by the operator. In some clinics ethylene has been found entirely satisfactory but has not received general adoption. Rectal anaesthesia, that is, the introduction of a certain amount of oil mixed with a given quantity of ether, introduced into the rectum, is employed at certain clinics in operations upon the jaws, tongue, larynx or that part of the gullet lying in the neck. In former years, various types of complicated, cumbersome differential pressure apparatus were used to prevent collapse of the lung and assure sufficient aeration when the pleural cavity was opened. Later intratracheal anaesthesia and still later intrapharyngeal anaesthesia was found to accomplish the same result in a far simpler manner. Nowadays the mask of a laughing gas-oxygen-ether apparatus is entirely adequate for this purpose. (See THORACIC SURGERY.)

*Local Anaesthesia*.—When cocaine was practically the only substance known for this purpose, its field of usefulness was limited because of its high toxicity. Since then a host of less toxic substances have been discovered, chief among which is novocain, and the field of applicability has greatly widened. A solution of 250 c.c. of  $\frac{1}{2}$  of 1% of novocain may be used in an adult weighing 150 lb. without danger. Solutions of even 0.1% are effective. (See Gaston Labat (W. B. Saunders, Pub.), *Regional Anaesthesia*, 1923.)

*Regional Anaesthesia*.—A local anaesthetic acts by virtue of its power to deaden nerve tissue, either at the sensory endings of nerve fibre (local infiltration), or along nerve trunks. For example, a few drops of solution in the eye renders the surface of the eyeball insensitive; or injected into the substance of the skin (raising a wheal) makes the injected area anaesthetic. For rendering greater areas insensitive it is more practical to deaden nerve trunks at a distance from the region to be operated upon (block anaesthesia) or even at their exit from the spinal canal (paravertebral anaesthesia; caudal or epidural anaesthesia). Carrying this principle to its logical conclusion, the anaesthetic solution may be injected into the spinal canal, thus rendering sensation of the entire body inactive from the level injected downwards. Spinal anaesthesia is applicable for the lower half of the body. It must not reach upwards because of danger from paralysing the vital centres in the medulla oblongata. The addition of adrenalin (epinephrin) to solutions of local anaesthetics is of advantage in that it lessens diffusion by local contraction of capillaries; in other words, keeps the solution at the place it should function and slows the rate of absorption by the tissues. Magnesium sulphate is advocated by some authorities as an adjunct to local anaesthetics. The conscious patient's apprehension is the only disadvantage of local anaesthesia. This may be largely avoided by exhibition of morphine or codein in maximal doses shortly before the operation. Scopolamine, a drug in vogue a few years ago, has been gradually discarded. It was the drug employed for inducing "Twilight Sleep" in labour.

The combination of local anaesthesia, general anaesthesia and analgesia induced by such drugs as morphine is being more widely used as time goes on. The surgeon's experience dictates their indication or limitation in each individual case. For example, if a patient suffers from acute tonsillitis and acute appendicitis the abdominal wall may be opened under local anaesthesia, the appendix actually removed under general anaesthesia, and the abdomen closed under the original established local anaesthesia. Thus the chances of post-operative pneumonia are minimised.

## OPERATIVE TECHNIQUE

Aseptic technique, now universally adopted, has reached a high state of efficiency. Operators invariably wear caps and masks, sterilised long-sleeved gowns and rubber gloves. All skin is potentially infective, no matter how its cleansing be accomplished. In recognition of this principle, the surgeon after scrubbing and disinfecting his hands and forearms to well above the elbows, dons sterilised long-sleeved gowns and rubber gloves. Likewise it is often customary to fasten sterilised towels to the wound's margin, after incising the skin, to prevent possible contamination of the deeper tissues. The steam-pressure steriliser in which gowns, gloves, gauze and drapings are sterilised, may at times be carelessly operated by unskilled attendants. To make certain of absolute sterility at all times, steriliser controls are inserted in the centre of all packages before being placed in the steam-drum. These controls are sealed glass tubes containing small cylindrical red pellets of material fusible at a temperature somewhat higher than actually necessary for adequate sterilisation. The surgeon can thus determine whether sufficient heat to produce adequate sterilisation has reached all parts of the package.

The sterilisation of instruments is easily accomplished by boiling in water to which carbonate of soda has been added. The addition of soda prevents rapid rusting of steel upon exposure to air after being boiled. Usually instruments are sterilised for 15 minutes to assure absolute sterility. (The spores of tetanus and anthrax bacilli are capable of withstanding boiling water for at least three minutes.) Sterilisation of edged instruments like scalpels is accomplished in some clinics by boiling in paraffine oil, while in others, chemical sterilisation by means of carbolic acid or one of its derivatives, is customary. Keen-edged knives are somewhat dulled by boiling in soda solution.

*Suture Materials*.—Strands of sterile catgut in sealed glass tubes are universally employed throughout the United States. These are furnished in two varieties: in one, boiling does not weaken tensile strength; in the other it does, and the tubes of this variety must be sterilised by long immersion (storage) in strong antiseptic solutions. Absorbable suture material is used for repair of deeper structures, whereas non-absorbable material,<sup>1</sup> such as silk, silkworm gut and horsehair, is mainly employed for suturing the skin. On the continent of Europe, in many clinics, fine silk is still used for ligatures and sutures in the depths.

*Clinical Antisepsis* (see ANTISEPTICS).—Alcoholic solution of iodine (tincture of iodine) or alcoholic solution of picric acid is now used for disinfection of the skin of operative fields, having supplanted the cleansing with soap and water followed by benzene, alcohol and ether. Some time before operation, however, it is necessary to shave and wash the operative field, thus allowing time for the skin to dry. This is essential to assure adequate penetration by the alcoholic solution of iodine or picric acid, which has been found much less effective when applied to the wet skin. Dakin's solution still holds a pre-eminent position in the antiseptic treatment of infected or potentially infected wounds. A host of other antiseptics, such as acriflavine, rivanol and mercurochrome, have many strong individual adherents, but not one has gained universal adoption.

The silver salts (silver nitrate, argyrol, protargol, collene and others) still hold their pre-eminent position in the treatment of infections of the mucous membranes of the eye, nose and throat,

<sup>1</sup> Also furnished in sealed glass tubes by manufacturers.

bladder and urethra and so forth. The greatly prolonged use of silver nitrate; either as a gargle when small quantities often are inadvertently swallowed, or for irrigation of large cavities lined with granulation tissue, may result in considerable absorption; as a consequence there is a general staining of the body tissues naturally most apparent in the skin and whites of the eyes. The staining is absolutely permanent and the condition is termed argyrosis, examples of which are sometimes seen in the "blue man" of the circus.

Bichloride of mercury (corrosive sublimate) is still used in disinfecting solutions for the surgeon's hands and forceps after thorough and prolonged scrubbing with soap and water. It has been abandoned, however, in solutions for irrigations and local wet dressings. Left in contact with the skin, it is apt to give rise to marked irritation, "bichloride dermatitis," and, if left filling large abscessed cavities, its absorption has given rise to systemic mercurial poisoning.

Carbolic acid likewise has been greatly restricted in its application. It is still used to disinfect sharp-edged instruments and in some clinics for its cauterising effect upon the stump of the appendix. In weak solution, as wet dressing for injured fingers, it is especially dangerous. Beneath this wet dressing the skin of the finger becomes insensitive and, if the solution be applied long enough the entire thickness of the skin or even the entire digit dies and eventually sloughs off. This condition is known as carbolic gangrene, pictures of which may be seen in the older text books on surgery. Carbolated vaseline may likewise cause carbolic gangrene. Absorption of weak carbolic solution by prolonged contact with raw surfaces may lead to absorption and general poisoning. Smoky urine, that is urine clouded with disorganised tissue and blood cells from the damaged kidneys, causing a brownish colour, is one of the typical symptoms of this condition. Hydrogen peroxide as an antiseptic in small accidental wounds is probably utterly valueless. Tincture of iodine, alcoholic solution of picric acid, acetic acid (even household vinegar which is diluted acetic acid), are far more effective antiseptics for accidental wounds.

*Preparation for Operations.*—In the presence of acute respiratory infections, general anaesthesia is contraindicated. During severe influenza epidemics, no operations except those of an emergency, life-saving nature should be undertaken. If the operation is not urgent, one waits until the coryza or bronchitis has subsided. On the other hand, if an operation is imperative, as much as possible is done under local anaesthesia and if general anaesthesia must be given, the use of nitrous oxide and oxygen would be least likely to be followed by post-operative pneumonia.

The stomach and intestines should be empty. If general anaesthesia is administered to a patient with a full stomach, he is sure to vomit while semi-conscious. Some of the vomited material may be drawn into the larynx, leading to immediate suffocation if the inspired material is a bolus of food. If the vomitus is fluid, it reaches the lungs and by infecting them may readily lead to pneumonia. For non-urgent operations, it is easy to have the alimentary tract empty by administering a cathartic and withholding food for a few hours before operation. Before emergent operations, the stomach is emptied by the passage of a stomach tube, followed by gastric lavage, and the intestines may be emptied by an enema. The bladder must be emptied either by the patient's own act or, if this is not possible, by catheterisation. A full bladder fills the pelvis and hampers proper exposure of the pelvic organs.

Upon completion of the operation, the patient is swathed in warm blankets to prevent chilling. Upon reaching his bed he is laid flat upon his back with head turned to one side to avoid possible aspiration of vomitus until consciousness is regained; only then may a pillow be placed beneath the head. In the presence of shock, the foot of the bed is raised to facilitate circulation to the vital centres in the brain. Warmth is maintained by hot-water bags wrapped in flannel, in addition to blankets. Particular care is taken that these bags are not so hot as to burn the unconscious subject. Stimulation is administered by a suitable hypodermic injection or by intravenous administration of normal saline

solution or 5% solution of glucose. Transfusion of blood is also given if needed.

The administration of water is of prime importance. Usually within a few hours, small amounts may begin to be given.<sup>1</sup> At times, however, the nature of the operation or the condition of the patient forbids administration of water by mouth. The rectal administration of water either by a continuous drip or at the rate of one pint every two hours, slowly given so as to be retained, is an excellent means of furnishing needed fluid. Still another method is by hypodermoclysis; that is, under aseptic precautions, either normal saline solution or preferably sterile water containing 0.05% novocain (25 c.c. of 0.5% novocain in 500 c.c. of sterile water) is injected subcutaneously as often as may be needed.

*Diet.*—There is no urgent necessity for feeding the average patient for four or five days after operation, provided he gets enough fluid. Nourishment is gradually resumed, beginning with the more easily digested fluids and gradually coming to the customary articles of everyday character.

*Treatment of Operative Wounds.*—Clean wounds in the usual course of events are not disturbed until it is time to remove skin sutures. Infected wounds are dressed as often as required, at least once every day, sometimes more frequently. Under ideal conditions of drainage, all the discharges are to be found in the dressings, in other words there is no welling up of pus from the depths of the wound upon exposure. In short, the age-long rule of adequate drainage in the presence of infection holds to-day as it ever will. The continuous instillation of improved antiseptic solutions is often a distinct aid, but is of no avail unless retention of pus is avoided by the establishment of proper facilities for adequate drainage. The mechanical devices for providing rest and elevation without hindering access to the wound, particularly in surgery of the extremities, cannot be described for lack of space.

Post-operative accumulation of gas, causing abdominal distention and cramps, may be controlled by applying turpentine stupes, and inserting a rectal tube, and by giving hypodermic injections of pituitrin,<sup>2</sup> and enemas of varying composition and quantity. Under ordinary circumstances, after an abdominal operation, a patient may be allowed out of bed at the end of two to three weeks, depending on his personal condition and the nature of the operation. It is not uncommon for the feet and ankles to swell for a short time, a day or two after getting up. If warned of this possibility and its spontaneous regression, much unnecessary alarm may be avoided. Realising that few persons are physically capable of resuming their ordinary occupation immediately after leaving the hospital, the social welfare departments established in all large clinics arrange for post-convalescent recuperation of from one to several weeks, and thus assist the patient to resume his natural course of life in restored health and strength.

#### NEUROLOGICAL SURGERY

With the exception of certain tumours of the cerebellar-pontine angle, the localisation of brain tumours was in an unsatisfactory state until the introduction of ventriculography by Dandy of Johns Hopkins. By means of this method, the ventricles of the brain filled with air may be depicted by Röntgen ray. Distortions from the normal, in size, symmetry and so forth, furnish most valuable clues regarding the site of the tumour although the growth itself is not visible. Combined with this great diagnostic advance, one sees wider exposure of the operative field and more radical and extensive intervention.<sup>3</sup> As material accumulates and experience grows, the classification of brain tumours is undergoing revision. The palliative operation of subtemporal decompression, designed to relieve increased intracranial pressure incident to a brain

<sup>1</sup> Water or tea as warm as possible, when given by mouth, is far less likely to cause gas pains than the ice-cold drinks which the patient so often requests.

<sup>2</sup> Pituitrin is a powerful stimulant of smooth muscle and must not be given in the presence of any mechanical obstruction to the passage of intestinal contents.

<sup>3</sup> Large sections of brain have been removed from so-called silent areas without affecting normal function.

tumour, is much less often practised than formerly. Several ingenious methods have been devised to reach the rather inaccessible pituitary fossa at the base of the skull. Operations for relief of enlargements of the pituitary gland show results which have mostly been palliative.

Surgical diseases of the spinal cord, in contrast with those of the brain, present fewer diagnostic difficulties and are much more easily approached. The operation of laminectomy consists of removal of vertebral spines and laminae in order to open the dural sheath longitudinally, and bring the spinal cord into view. Further operative procedure depends upon the conditions encountered. For relief of intractable facial neuralgia, extirpation of the Gasserian ganglion has now been supplanted by a simpler, safer, Frazier-Spiller operation consisting of simple division of the ganglion's sensory root. There is practically no mortality, in striking contrast to the method it has supplanted. Paralysis of the facial nerve may be relieved by anastomosis with some other readily accessible motor nerve in the neck. The paralysed half of the face regains its normal appearance in repose, but mimetic control rarely reaches perfection.

In surgery of the peripheral nerves (see also ORTHOPAEDIC SURGERY), the repair of damaged motor nerves constitutes the main part of this field. The nerve cells lie in the spinal cord and from there send their prolongations (aggregations of which constitute the peripheral nerves) to all parts of the body. If a severed nerve is reunited, the active nerve elements begin to grow from the point of division downwards along the paralysed peripheral trunk until they reach the motor end-plates in the muscles normally supplied. The rate of growth is slow, and meanwhile the paralysed muscles must be kept in a relaxed (not overstretched) state by suitable orthopaedic appliances (splints, braces and so forth). Severe injuries to nerve trunks of the extremities often result in considerable loss of substance; consequently the nerve ends may lie several inches apart.

Approximation of the separated ends may be facilitated by suitable changes in posture; for example, flexion in defects of the median or musculo-spiral nerves, or extension for defects of the ulnar nerve, may overcome gaps of one or two inches. Position thus favouring approximation must be maintained for several weeks until healing is assured, and only then may there be a gradual relaxation to normal. Nerve cabling has been used to bridge longer gaps. Results are still inconclusive. A length of purely sensory nerve is excised; this is then divided into shorter lengths just sufficient to bridge the gap. These are laid together to form a cable of diameter equal to the trunk being repaired. If the torn nerve ends are buried in a mass of scar tissue<sup>1</sup> dissection is begun both above and below this point to expose the uninjured nerve in its normal relations, and from these points both ends are traced to their termination in the scar. They are then laid back and the scar itself is excised. If within the nerve ends themselves there is much cicatricial tissue, cross sections are progressively removed, until normal nerve tissue is exposed; only then should anastomosis be attempted. The recently revived and elaborated operations on the sympathetic system are still in the experimental stage. While the one devised to relieve the pain of angina pectoris accomplishes its purpose, it is to be remembered that the basic pathological changes in coronary arteries and heart muscle remain and pursue their course.

#### VARIOUS TYPES OF SURGERY

*Surgery of the Face.*—Cosmetic and plastic surgery, especially of the face, has undergone considerable improvement following our large experience in the World War. By transplantation of skin, cartilage, bone and fat, results have been accomplished which by ordinary plastic methods would have been impossible. Fractures of the jaws are best treated by dentists and oral surgeons whose mechanical appliances are most effective in maintaining correct alignment and approximation of fragments.

<sup>1</sup> It is unsafe to re-operate after prolonged suppuration for at least one year after healing. Viable pathogenic bacteria persist in the scar, and premature operation releases them with resultant infection and failure of the operation.

*Surgery of the Nose and Throat.*—Tonsillotomy, amputation of the projecting prominence of the enlarged tonsil, is obsolete, because it was found that the remaining deeper portion of the tonsil still acted as a source of infection. Tonsillectomy (enucleation, that is, shelling out of the entire tonsil from its bed) is now universally preferred. General anaesthesia is preferable for this in children. By means of a suction tip-used throughout the operation, mucus and blood are constantly removed from the back of the throat and the aspiration of material into the bronchi and lungs prevented. Prior to routine use of suction, lung abscess following removal of tonsils and adenoids was not uncommon. Adenoids if completely removed in infancy occasionally recur in later childhood.<sup>2</sup> Tonsillectomy in adults is usually performed under local anaesthesia. Recovery requires more time than in children. Experience has shown that chronic infections of the upper respiratory tract (of the tonsils and adenoids and also of the accessory air sinuses such as the ethmoid and frontal sinuses and antrum of Highmore) lead to continual reinfection of the bronchi and lungs. Therefore in every case of so-called chronic bronchitis, all foci of infection in the upper respiratory tract should be found and treated. The lungs will then often heal of their own accord.

*Use of the Bronchoscope.*—The recent development of bronchoscopy marks a great advance in the diagnosis and treatment of pulmonary disease. The bronchoscope, a long smooth tube of suitable calibre, illuminated at its distal end by a small hooded electric lamp, is introduced through the mouth and larynx down the trachea to its bifurcation; deviation of the instrument to either side then permits further introduction and inspection of the bronchus and its smaller branches. By means of bronchoscopy the following may be accomplished: (1) removal of foreign bodies, some of which such as wooden objects are not revealed by the Röntgen ray; (2) recognition of growth, small pieces of which may be secured for microscopical examination and diagnosis; and (3) localisation and treatment of lung abscesses, especially those lying close to the root of the lung. By introduction of a suitable small tube through the bronchoscope into an abscess, its purulent contents may be removed by suction, and appropriate antiseptics in either powdered or liquid form may be injected under control of the eye. A certain proportion of lung abscesses heal spontaneously. Another group, especially those lying near the hilus, may be cured by the bronchoscopic treatment just described, while a third group, chiefly those lying in the peripheral lung tissue, finally require surgical drainage for their cure by approach and exposure through the thoracic wall and intervening lung tissue. (See *Surgery of the Thorax* below.) All lung abscesses should first be given the benefit of bronchoscopic treatment and only when this proves ineffective should operation be resorted to. After the World War quite a number of patients presenting symptoms of cough, profuse expectoration, fever and wasting, who were received at sanatoria for pulmonary tuberculosis, eventually proved to be cases of lung abscess. Mistaken diagnosis of this sort is not uncommon to-day.

*Use of the Esophagoscope.*—Esophagoscopy is identical with bronchoscopy except that the instrument is introduced into the esophagus instead of the trachea. By means of this the following may be accomplished: (1) removal of impacted foreign bodies, (2) recognition and exact localisation of diverticula (abnormal pouches or sacculations in which food may accumulate and stagnate) and (3) determination of the benign or malignant character of strictures. Intrinsic strictures of the esophagus may arise from one of three causes: (1) cardiospasm, a functional spasm of the cardia where the gullet enters the stomach; (2) cicatricial contraction of a healing or healed ulcer usually caused by accidental (or suicidal) swallowing of caustic alkalis or acids; and (3) narrowings from encroachment upon the calibre of the gullet by new growths usually cancerous. Extrinsic causes of esophageal obstruction, that is, pressure upon this tube from without, may be due to aneurism of the aorta, tumours of the mediastinum

<sup>2</sup> A child who is an habitual mouth-breather, especially while asleep, may reasonably be suspected of obstruction of the back of the nose by hypertrophied adenoid tissue.

and so forth, in which event the esophagoscope reveals normal conditions within this passage.

*Surgery of the Neck.*—Local anaesthesia is much more extensively used than in former years for operations in this region. Since the introduction of diphtheria antitoxin and intubation, the occasions for tracheotomy have greatly diminished. (Up to the early eighties tracheotomy for diphtheritic laryngeal obstruction was a common emergent procedure.) Laryngectomy for intrinsic carcinoma of the larynx affords an excellent prospect for permanent cure in early cases. Diverticula of the esophagus lying in the neck are more easily located at operation by co-operation between bronchoscopist and surgeon, the former inserting his lighted instrument into the pouch when the latter has reached deeper layers of the neck from without. Block dissection of the fascia and lymph nodes of the neck is practised in conjunction with operations for carcinoma of the face and oral cavity. (see *Cancer* above). Growths in this region tend to spread locally by way of the lymphatics (necropsy in cases of cancer in this region rarely show extension to distant parts of the body). Hence it is logical to exert every means of preventing local recurrence as just indicated.

Rupture of the brachial plexus (of nerves) is most commonly seen as birth palsy. Exploration and exposure of nerves to the arm as they emerge from the spinal column at the root of the neck, reveals one of two conditions: either the nerves have been torn across at some point between the spinal column and where they pass down to the arm under the clavicle, or their roots have been torn out of the spinal cord. In the former event, the torn ends may be united with good hope of ultimate recovery. In the latter case, the injury is irreparable. Surgical exposure offers the only means of determining which condition exists.

Phrenicotomy (division of the phrenic nerve in the neck) is said to paralyse the corresponding half of the diaphragm; it is sometimes practised in conjunction with other means of putting one lung at rest (see *THORACIC SURGERY*; also *SURGERY OF HEART AND LUNGS*). Röntgenograms of structures in the neck may demonstrate such conditions as narrowing and distortion of the trachea by compression from enlargements of the thyroid gland, diverticula of the esophagus, accessory ribs (occasionally causing neuralgia of the brachial plexus) and fracture or disease of the cervical vertebral structures. (see *PHYSIOLOGICAL ANATOMY* (J.C.A.G.).

*Surgery of the Thyroid Gland.*—The mortality of operation on the thyroid gland compares favourably with that of any in major surgery. Statistics show that, computing operations, a mortality rate of 0.95% has been attained, and computing cases, a rate of 1.2%. The diseases of the thyroid gland amenable to surgery may be grouped under six headings: (1) diffuse colloid thyroid, (2) adenoma without hyperthyroidism, (3) adenoma with hyperthyroidism, (4) exophthalmic goitre, (5) thyroiditis and (6) malignancy. Diffuse colloid goitre is a physiologic enlargement of the thyroid gland occurring in adolescence, caused by insufficiency of iodine and cured by the administration of iodine or thyroxine. Unless colloid goitre is associated with adenoma, or by its size causes pressure symptoms, operative treatment is not indicated. Adenoma without hyperthyroidism should be treated surgically, partly for cosmetic purposes when the goitre is unsightly and for the relief of pressure symptoms, and partly because a certain proportion of patients subsequently develop hyperthyroidism. The operative risk is less than 0.5%, and the operation results in cure in practically 100% of cases.

If adenoma of the thyroid gland is complicated by hyperthyroidism, the onset is usually so insidious that operative treatment is not sought until marked degeneration of important organs has taken place; this increases the operative risk and diminishes the chance for complete cure. The operative mortality in this stage has been found to be between 2 and 4%. Operation results in cure in about 83% and in marked improvement in another 5%. Exophthalmic goitre is a constitutional disease apparently due to an excessive (probably abnormal) secretion of the thyroid

gland, and while its cause is unknown, treatment aims to diminish the activity of the gland. As a result of increased knowledge of the disease and of the dangers incident to operative treatment, and since patients with exophthalmic goitre are coming to operation earlier, before the development of changes in other organs, the surgical mortality has been reduced to practically 1% in terms of operation and 1.74% in terms of cases.

The natural fluctuating course of the disease makes it difficult to evaluate any form of treatment, unless sufficient time has elapsed to preclude the probability of recurrence. Study of the results about five years after operation shows that 90% of the patients were living, 79% considered themselves cured or greatly improved by the operation, 8% were improved but showed evidences of hyperthyroidism or its effect, and 3% were not benefited. On analysis, lack of improvement could be traced definitely to three causes: (1) incompleteness of operation, (2) the long duration of hyperthyroidism before operation and (3) failure to eliminate foci of infection after operation. Thyroiditis is rare, and operative treatment is indicated only in the tuberculous and suppurative types.

Malignancy occurs as sarcoma, carcinoma, malignant adenoma and malignant papilloma, in the ratio of one malignant case in 57, and the prospect of cure by operation and intensive treatment with radium and Röntgen ray varies with the type of malignant disease. (see *PHYSIOLOGICAL ANATOMY* (J.C.A.G.). (C.H.M.)\*

*Surgery of the Breast.*—Cancer of the breast still takes its yearly toll of thousands. Statistics indicate that in cases where the axillary lymphatics are not as yet involved, prospects of cure are far more favourable. As said elsewhere, periodic physical examination, annually at least, is our best means of protection. In doubtful cases of tumour of the breast, the surgeon removes a small section of the growth for rapid microscopical examination (by the so-called frozen-section method) and receives a report within a few minutes. Local excision or radical amputation is accordingly carried out depending on whether the growth has proved benign or malignant. Small benign tumours of the breast may be removed without cosmetic deformity, either through an incision within the vermilion border of the mamilla (the pigmented area surrounding the nipple) or through a curved incision corresponding to the lower fold of the breast.

*Surgery of the Thorax.*—Röntgen-ray diagnosis of disease in this region has made great advances during the last 15 years. While nearly all the conditions about to be cited could be clinically recognised in earlier times, the additional knowledge furnished by the Röntgen ray is of such great value that it is practically indispensable. Lack of space forbids detailed discussion; however, among the more important conditions are: lesions (fractures, chronic inflammations or tumours) of ribs, spinal column, breastbone (sternum) or collar bone (clavicle); pneumonia, lung abscess; bronchiectasis, empyema (recent or old), tuberculosis, tumours, either originating in the lung or secondary to cancer elsewhere (for example, secondary to sarcoma of a bone or carcinoma of the breast), paralysis of the diaphragm, hernia of the diaphragm permitting partial escape of abdominal viscera into the thoracic cavity, enlargement of the heart, effusion in the pericardial sac, aneurism of the aortic arch, stricture and diverticulum of the esophagus, tumour of the mediastinum and, lastly, foreign bodies lodged in gullet or air passages by accidental swallowing or inhalation or introduced into the thorax as the result of external violence following shooting, stabbing, explosions and so forth.

*Safeguards in Operations Upon the Opened Chest.*—The thorax may be considered a bellows containing two collapsible bags, the lungs, between which lies a flexible partition, the mediastinum. If a sizable opening be made in one wall of this bellows, the exposed lung collapses, the to-and-fro action (respiration) goes on, but the amount of air drawn in and blown out of the remaining lung is greatly diminished, because on inspiration the mediastinum is drawn over toward the uninjured lung, and on expiration it is pushed over toward the opened side of the chest. To afford an adequate exchange of air a slightly increased pressure of air or diluted oxygen in the upper respiratory tract (mouth and nose)

\* Intrinsic implies that the growth is still within the larynx, in contradistinction to extrinsic when the laryngeal growth has extended and involved soft parts of the neck as well.

prevents entire collapse of the lung and provides adequate aeration. (See also discussion of differential pressure under *Anaesthesia* above.) In emergencies, in the absence of differential pressure apparatus, this mediastinal flutter may be controlled by grasping and steadying the lung of the opened side; this prevents excursions of the mediastinum and permits air to be drawn into the lung of the opposite side. (For many years Australian surgeons have employed this measure when removing echinococcus cysts of the lungs, and more recently in the World War the French also used the same procedure when operating for removal of foreign bodies such as bullets and shell fragments.) Tight closure of the chest wall at the end of the operation is all that is requisite.

Compression pneumothorax may follow a smart compression not quite severe enough to crush the chest. Rupture of lung or bronchial tissue permits valvular escape of air into the pleural cavity with each respiration. As air accumulates, it not only compresses the lung on the affected side but also displaces the heart and mediastinum towards the opposite side and this interferes with the function of the other lung as well. Permanent suction applied by an aspirating needle thrust into the pleural cavity will control this condition (the blood-clots, sealing tears in lung tissue, are found to be especially tenacious). Sometimes rupture of bronchi from the same cause (compression of the thorax) results in escape of air into the mediastinal tissues instead of the pleural cavity, and by continued accumulation produces subcutaneous puffing of the neck and face. In a case of this sort a wound may be established in the episternal notch and a glass suction-cup arranged to connect it with a vacuum pump (Tiegel). In a few hours the condition subsides.

Empyema of the pleural cavity is a common sequel of pneumonia. Experience with large numbers of cases of empyema among the United States soldiers in the winter of 1917-8, during the great influenza epidemic, established a rule that while cloudy fluid should be removed by aspiration as often as necessary, actual operation should be deferred until pus has become thick and creamy. Nothing has been lost by such temporisation. The increased mortality from premature surgical drainage of accumulations of infected pleural fluid conclusively demonstrated this point. For the technique of open and closed drainage, various suction methods, sterilisation of the infected pleural cavity by Dakin's and other antiseptic solutions, and the use of "blowing bottles" to encourage expansion of the lung, the reader is referred to articles on empyema in the surgical literature.

Most empyema cavities gradually close as the lung expands, finally reaching the chest wall. In some, however, this expansion does not take place and a persistent cavity lined with granulations remains. The surgical obliteration of such cavities<sup>1</sup> constitutes a problem in itself. Decortication of thickened pleura covering partly collapsed lung (to permit it to expand) is rarely feasible, because dense adhesions with underlying lung tissue obliterate any plane of cleavage. Consequently mobilisation of the rigid chest wall is the method of choice. Removal (resection) of ribs from that part of the chest wall directly overlying the persistent cavity permits the soft tissues remaining to be brought into easy coaptation with the underlying lung. For details of operative procedure the reader is referred to textbooks and monographs on thoracic surgery.

*Lung Abscess.*—If medical and bronchoscopic treatment have not been successful, surgical drainage is effected (usually under local anaesthesia)<sup>2</sup> through an opening in the chest wall, by resection of a sufficient number of ribs (in part) to provide proper space for necessary manipulation. If pleural adhesions, that is, adhesions of lung to chest wall are present, the operation proceeds, the abscess is located by a long aspirating needle (upon withdrawal of pus), then, the needle left in place as a guide, the

<sup>1</sup> Rigid-walled granulating cavities will not heal. One or another of their sides must be mobilised so that coaptation of lining granulations is obtained. The same principle applies in the treatment of chronic osteomyelitis with persistent sinuses.

<sup>2</sup> This is safer than general anaesthesia which may permit pus from the abscess to enter uninfected regions of the lung instead of being coughed out as usual by the conscious patient.

vascular lung tissue is slowly divided with a cautery and the opening is deepened until the abscess is entered. A large drainage tube is then inserted. If no adhesions are present (between lung and chest wall) and drainage of the abscess is not imperative, which is rarely the case, it is safer to wait for several days until adhesions artificially produced by the surgeon are firm, after which drainage may be established as described. For other features of surgery of the lung and such methods of inducing collapse as extrapleural thoracoplasty, phrenicotomy and artificial pneumothorax. See HEART AND LUNG, SURGERY OF.

*Operations on the Esophagus.*—The intrathoracic esophagus lies in front of the vertebral column between the lungs and alongside of the aorta. For years, cancer of this structure was considered inoperable. In the light of present experience it can be stated that it is technically feasible to remove the growth, provided it is in an operable stage, but most patients come to the operating table too late: the cancer is found to have broken through the esophageal wall and to have involved adjacent vital structures so that its complete removal is impossible. Generally the patient has disregarded his difficulty in swallowing for months and only sought surgical relief when facing actual starvation. Thus, through ignorance, precious time has been lost when the growth might have been found removable. Improved results may confidently be expected in the cure of this otherwise fatal malady. Its palliative treatment consists in establishing a gastric fistula (gastrostomy) through which the patient is fed by tube, as is customary in cases of benign strictures of the esophagus.

*Surgery of the Abdomen.*—To no region of the body do the introductory statements regarding advances in surgery apply more pertinently than to the abdominal cavity. Intra-abdominal diseases which formerly masqueraded under a number of different names are now recognised to be one and the same thing. In X-ray investigation of the alimentary tract, suspensions of barium sulphate are administered by mouth in the form of opaque meals which fill the stomach, outlining this organ and then, as time goes on, pass into the small and finally into the large intestine. The large intestine, however, may be more clearly depicted by means of a barium enema, and this method is preferable when chronic intestinal obstruction is suspected; the fluid barium meal taken by mouth loses much of its water as it collects above a point of narrowing, and so is converted into a putty-like mass which may block a narrow opening, thus suddenly changing a chronic into an acute intestinal obstruction.<sup>3</sup> The Graham method of depicting the gallbladder depends upon the functional ability of this organ to concentrate bile. The sodium salt of phenoltetraiodophthalein administered by mouth is excreted in the bile and concentrated in the gallbladder. Aberrations from the normal picture, when considered with the history and clinical findings, in many instances permit the accurate diagnosis of cases in which it was previously impossible. In the urinary tract, solutions of sodium iodide enable one to see the outlines of the bladder, ureters and pelves of the kidneys (see UROLOGY). Free gas in the peritoneal cavity occurring in the course of disease or following injury, indicates that an opening is present somewhere in the walls of stomach or intestines. For example, in cases of acute perforation of a gastric or duodenal ulcer, roentgenograms taken with the patient upright will show a thin crescentic layer of gas beneath the diaphragm and above the liver. Such a finding may also occur after non-penetrating injury<sup>4</sup> of the abdomen with rupture of intestine.

It is a difficult matter at times to decide whether or not to operate in the presence of these abdominal contusions, and such an X-ray finding is of the utmost value. On the other hand, if an exploratory operation be decided upon, under conditions where the roentgenogram is not available, when the peritoneum is exposed, the wound is filled with sterile water so that when the peritoneum is nicked, the escape of gas may be seen immediately.

<sup>3</sup> Such a complication is most undesirable because operations for relief of acute intestinal obstruction are always associated with higher mortality and graver complications than those for chronic obstruction.

<sup>4</sup> Air anywhere within the body is absorbed within a few hours.

In all cases in which the abdominal cavity is opened surgically for relief of non-suppurative disease, it is customary for the surgeon to introduce his hand into other regions than that immediately concerned. This procedure requires but a few moments and is of the utmost value in determining the presence or absence of other intra-abdominal lesions. Naturally in the presence of acute or chronic suppuration, manual exploration of other regions is unwise for fear of spreading infection.

**Hernia.**—The abdominal wall may be considered to have three layers: (a) a smooth, glistening, internal lining of no intrinsic strength, the peritoneum; (b) a musculo-aponeurotic wall of great strength which has points of potential weakness (in the groins and in the region of the umbilicus, for example); and (c) the overlying elastic skin. A bulging of the distensible peritoneum through such an unduly weak opening in the strong musculo-aponeurotic wall, permits the protrusion of a peritoneal sac containing structures normally lying in the abdomen such as omentum and intestines. The potential danger of a hernia is the possibility of strangulation of its contents by the inelastic ring at the neck of the sac. Operation for the repair of a hernia consists in exposure of the parts, opening of the sac, replacement of the sac's contents within the abdominal cavity, closure of the sac at its neck, amputation of its now redundant portion and, last but not least, closure of the opening in the musculo-aponeurotic layer. The principle of overlapping tissue layers of the musculo-aponeurotic wall, like buttoning a double-breasted coat, is generally accepted at present.

In large hernias especially those occurring in scars from previous laparotomy, the use of fascia lata from the outer side of the thigh, either as strips for suture material, when the opening can be closed without undue tension) or in sheets (when the edges of the hernial ring cannot be readily approximated), is gaining general adoption. The reader is cautioned not to consider the subject of hernia as covered by the above elementary remarks, and particularly not to draw conclusions from any single case until he has familiarised himself with all contributory and complicating factors of this field by a study of the technical literature.

(J. C. A. G.)

**Surgery of the Stomach and Duodenum** (see also APPENDICITIS).—Each year the surgical treatment of diseases of the stomach and duodenum shows, in some respects, definite progress. Much of the recent advance in the efficient management of gastric and duodenal disorders has been due to: (a) increasing ability to detect existing disease process; (b) better interpretation of the significance of the clinical findings; (c) better judgment in deciding on the management of the complicated cases; (d) quick recognition and control of serious complications, particularly gastro-intestinal stasis, and (e) increasing experience in the operative treatment of surgical lesions.

The diagnosis of benign lesions of the stomach and duodenum can be correctly made by a proper correlation of clinical and roentgenologic findings in about 96% of cases, and of gastric carcinoma in about 98%. The indications for operation in cases of uncomplicated chronic or recurring duodenal ulcer are positive when the symptoms cannot be relieved or controlled by medical means. In cases of gastric ulcer, operation is always indicated unless adequate contraindications exist, and in gastric carcinoma, exploration is advisable if the disease is not obviously irremovable or incurable.

There are various methods of treating ulcers because lesions of the duodenum unquestionably heal spontaneously under various forms of medical regimen; others continue into a chronic state which can only be relieved by surgical measures. The most commonly performed operation is gastro-enterostomy. This procedure insures a permanent cure in between 80 and 90% of the cases, and such a high percentage of cures accounts for such frequent recourse to this operation. There is, however, a certain percentage of failures, so that other types of operation have been devised. The more important of these are operations at the outlet of the stomach which remove the ulcer and part of the pyloric muscle, and provide for adequate drainage of the stomach. Recently the removal of part of the stomach has been advocated

to prevent recurrence of ulceration. This operation has gained very little popularity because of its radical character, and because the general principle of removing a considerable part of the stomach for a lesion which is not in the stomach does not seem reasonable.

In chronic gastric ulcer prolonged medical treatment is justified only when surgical treatment is absolutely contraindicated by the age or the condition of the patient. As a temporary expedient, however, medical treatment may be not only justifiable but of marked value in improving the general condition when the surgical risk has been aggravated by repeated hemorrhages, extensive subacute local inflammatory changes, or toxemia from gastric retention. The danger of malignant degeneration of gastric ulcer should not be minimised, and it becomes imperative, therefore, to make a real effort to remove the lesion. This can be done either by local excision or by partial gastrectomy; and of the various procedures in common use excision of the ulcer combined with gastro-enterostomy and resection of a considerable portion of the stomach are the most widely advocated. The results of this form of treatment are excellent.

The successful treatment of gastric carcinoma depends on early diagnosis because of the insidious onset of the disease. Those which develop at the pyloric end of the stomach are most suitable for removal. They give the best prospects of cure and, fortunately, cause symptoms early. In almost half of the cases in which operation is advisable the growth can be removed and a prospect of cure assured. In over 50% of the cases in which the growth is removed and in which the disease is confined to the stomach there is an assurance of at least a three-year cure. In the treatment of acute perforation of duodenal or gastric ulcers the patient's life may be almost certainly saved if operation is carried out in the first few hours after perforation has occurred. Closure of the perforation is the only procedure necessary to save the patient's life; but if his condition warrants it at the time, other procedures may be combined with it to protect him against ulceration in the future. Operations on the stomach are also carried out for benign tumours, occasionally for foreign bodies (usually swallowed by insane persons), and occasionally for the curious hair-ball tumours which form in the stomachs of persons who are in the habit of biting and swallowing hair. (D.C.B.\*)

**Surgery of the Colon.**—The colon is an important part of the intestinal tract, and yet any part or all of it may be sacrificed without serious consequences and without interfering greatly with the comfort of the patient. When it is removed its physiologic functions are compensated for to a certain degree. The many lesions affecting the colon may be grouped according to the nature of the condition, and for convenience of study as follows: (a) congenital deformities, such as extreme dilation of the colon resulting in Hirschsprung's disease or giant colon, and bands or kinks, which may have resulted from abnormal development; (b) inflammatory lesions (ulcerative colitis, tuberculosis, diverticulitis and actinomycosis); (c) benign tumours, either polypi, which occur singly or more often as multiple small tumours and sometimes as a diffuse polyposis, or, occasionally, adenoma of the lower colon, both seeming to have a tendency to develop into malignant tumours, and (d) malignant tumours, largely cancers. Cancer of the colon is common, and in the early stages can be removed satisfactorily.

Of the different tumours which may occur malignant tumours hold first place in importance because they are by far the most common tumours of the colon; operation affords the only prospect of cure, and surgical treatment is frequently difficult. The symptoms are usually manifested sufficiently early and are usually those of obstruction and of anaemia. The anaemia resulting from cancer in the cecum and ascending colon is frequently very marked, and may be so severe as to give rise to an opinion that the disease is incurable. Various methods have been devised for carrying out more extensive operations on the colon for malignant disease with the maximum of safety. Most of these are based on carrying out the operation in several stages. The prospects of cure in cancer of the colon are higher than in cancer in many other situations. About 50% of the cases of cancer of the

colon are found in the cecum and ascending portion; about 10% in the hepatic flexure; about 8% in the splenic flexure; about 13% in the descending colon, and about 20% in the transverse colon. Other diseases of the colon occasionally require operative treatment when they interfere seriously with its function; or resist medical treatment. The operation may consist of the removal of any part or all of the colon.

**Surgery of the Rectum and Anus.**—The skin about the anus is subject to lesions, more painful than serious, varying from slight cracks to fissures. Sometimes cleanliness and hot applications will cure them, but the ulcerated forms require excision. Fistula (fistula-in-ano) usually commences with inflammation of one of the crypts that surround the anus. The infection is trapped by the swelling and burrows along the side of the anal canal. An abscess may form in the loose tissue and may rupture into the rectum further up or externally on the skin near the anus. Tuberculosis is not nearly so common a cause as was supposed. The fistula must be opened, curetted and packed so that it heals from within outward. Usually this procedure cannot be carried out until the external sphincter has been cut.

Hemorrhoids may be either external or internal, or both. The external ones are covered by skin, the internal by mucous membrane. They are best treated by excision and ligation. The cautery is used for destroying internal hemorrhoids, but the painful after-effects make its use undesirable for external hemorrhoids. In certain cases injections of medicaments directly into the hemorrhoids are effective. Stricture results from injury, such as burning or unskilful operations, from infection, syphilis, tuberculosis and from new growths, especially cancer. Incision and gradual dilatation may cure, or the constricted zone may have to be resected and the ends anastomosed. Of all cancers in the colon, most occur in the rectum. Early diagnosis and prompt excision afford the only chance of cure. The operation is often performed in two stages. The signs of cancer of the rectum are similar to those of hemorrhoids, and in many cases of cancer the patient has undergone an operation for this apparently innocent manifestation of a serious disease. It is becoming a routine to examine the rectum and sigmoid with a proctoscope in all cases of hemorrhoids.

**Surgery of the Liver and Bile Passages.**—Symptoms of gallstones are often mistaken for those of gastric ulcer. Commonly, stones first form in the gallbladder and their presence is characterised by attacks of pain and vomiting without fever. A stone in any hollow organ of the body predisposes to subsequent infection, and gallstones follow this rule. As time goes on, stones are also found in the common duct (a much more serious condition), and jaundice is frequently observed following attacks of pain. There is a definite association between disease of the bile passages and acute hemorrhagic pancreatitis. The diagnostic value of the Graham test in pathologic conditions of the gallbladder has been outlined above in discussing X-ray diagnosis of intra-abdominal lesions. Cholecystectomy, that is, removal of the gallbladder, is the operation of choice when not accompanied by too much risk. Cholecystostomy, or opening and drainage of the gallbladder, affords temporary relief. It is an excellent measure under local anaesthesia for desperately sick patients who, however, generally require a secondary cholecystectomy for permanent cure. Conditions requiring operation on the common duct are of far more serious import than those on the gallbladder, generally speaking. The deep jaundice which so often accompanies obstruction of the common duct may lead to postoperative cholemic oozing, a most serious complication. Transfusion and the administration of calcium salts often but not invariably control this hemorrhagic condition which if unchecked results fatally. Stones may exist in the gallbladder and common duct without causing symptoms and the remarks made above apply only in the majority of instances.

**Surgery of the Spleen.**—The spleen is a very vascular organ. Its removal (splenectomy) for control of hemorrhage as the result of traumatic or spontaneous rupture, is an old, recognised procedure. Splenectomy is of benefit in the early stage of Banti's disease and in certain cases of hemolytic jaundice. In pernicious

anemia it is of little value as the remissions following splenectomy are but little longer than those after transfusion. Of recent years a form of purpura has been recognised in which the blood platelet count is low and fragility of the red blood cells is markedly increased. Spontaneous oozing of blood from all mucous membranes as well as typical subcutaneous hemorrhages whose blue colour first gave the condition its name, are accompanied by rapidly progressing anemia which soon leads to death. The almost instantaneous cessation of oozing immediately following splenectomy (occurring even before closure of the abdominal wound) is one of the most dramatic events in modern surgery. Transfusion before and afterwards is employed to sustain life and not to control the disease.

**Gynecologic Surgery.**—Refinements in operative technique have kept pace with those in other branches of surgery. Acute inflammations of the pelvis are conservatively treated. Indeed in many cases, pelvic inflammation may enjoy complete symptomatic recovery following sufficiently prolonged rest in bed and appropriate local measures. In the acute stage, if abscesses form they are drained, but otherwise nothing more radical is done. Operative removal of carcinoma of the uterine body gives excellent results. Regarding treatment of carcinoma of the cervix, a far more deadly form of the disease, there are two schools of thought at the present writing. One still favours operative treatment; while the other maintains that radiotherapy (by radium or the X-ray in massive doses) gives equally good late results. Regarding carcinoma of the cervix in stages beyond the possibility of operative intervention, there can be no question that radium is the means now universally adopted. The foul discharge dries up and the local tumour disappears and, although permanent cure is rare, the patient's existence is made infinitely more tolerable. Exposure of the ovaries to X-rays stops menstruation, and is often used in controlling excessive uterine bleeding. The Rubin test for determining patency of the uterine body and Fallopian tubes in cases of sterility is a recent innovation. When this test was introduced, air was injected through the cervix uteri and its presence or absence within the peritoneal cavity determined by the X-ray. Later experience showed that with a manometer to gauge the amount of air pressure employed, equally accurate determination could be made and X-ray control could be dispensed with. The use of foreign proteins in the treatment of pelvic inflammation is still in the experimental stage.

**Surgery of the Extremities.**—In the treatment of fractures (see ORTHOPAEDIC SURGERY) the time-honoured plaster cast still has its place. However, maintenance of proper alignment of fractures by suspension and traction has come into deserved repute, notably in fractures of the humerus close to the shoulder joint, and in the revived Hodgen's method for fractures of the femur. Skeletal traction, a further refinement, consists in metallic appliances (such as Steinmann pins, sharp-pointed tongs like ice-tongs, or Finocchio stirrups) which are attached to the bones at some suitable point below the site of fracture. By this means shortenings may be overcome which could not possibly be corrected by traction upon moleskin adhesive strips applied to the skin. These methods limit indications for open reduction to those cases with interposition of soft parts between the fragments (see also FRACTURES). Disuse stiffens joints and tendon sheaths. Consequently the manifold physiotherapeutic measures<sup>2</sup> which encourage active motion within the limits of pain, have their distinct use in promoting and accelerating return of function (see also ORTHOPAEDIC SURGERY).

Amputation of the lower extremity, if possible, is so devised as to furnish stumps capable of bearing weight directly on their ends instead of on the bony prominences of the joint next above the site of amputation (see descriptions of the Hirsch-Bunge method in surgical literature). Early active mobilisation after

<sup>1</sup> An operation for exposing displaced fragments, correcting their alignment and retaining correction by suture, metal bands, vanadium steel plates held in place by self-tapping screws of the same material, and so forth (see also FRACTURES).

<sup>2</sup> Warmth by baking whirlpool baths, diathermy (see ELECTROTHERAPEUTICS) and, natural or artificial heliotherapy, and so forth.

operations on joints (for example, after operations for removal of the internal semilunar cartilage of the kneejoint) gives excellent immediate functional results and is being more and more widely practised.

The Willems treatment of acute joint suppurations, if instituted early, preserves function and constitutes a notable advance. In former times, the most that could be hoped for was a stiff joint after weeks and even months of precarious convalescence. With the Willems method, generous longitudinal openings are made on either side of the affected joint, but no drainage tubing, gauze or other material is introduced into the joint cavity; there is no irrigation, but simply active motion every two hours which permits the free escape of purulent secretions and preserves function. As time goes on, the secretions gradually lose their purulent character and finally become clear, and the wounds close of themselves leaving a free healed joint. The method is of no avail when infection has spread beyond the lining synovial membrane and has involved the soft tissues of the joint outside.

Infections of the hand and fingers comprise an important and relatively neglected field of surgery. The different forms of infection should be recognised early; the proper and least disabling drainage incisions should be made, and voluntary motion should be begun at the earliest suitable moment, long before the drainage wounds themselves have begun to close. In no region does the retention of pus more rapidly destroy essential structures than in the hand and fingers.

In conclusion the reader is again reminded that a cursory review of surgery is all the limitations of this article permit, and that almost no justifiable conclusions regarding any single surgical incident in the reader's experience can be drawn by him from the contents of this article, because of innumerable, relative, qualifying surgical factors which may exist, unknown to the lay mind. The mutual dissatisfaction of lawyer and medical expert so often seen in the courtroom furnishes an excellent example of this. It requires years to train a surgeon, and one cannot condense all the knowledge so acquired into a few minutes' exposition of the subject. See also HEART AND LUNG, SURGERY OF; ORTHOPAEDIC SURGERY. (J. C. A. G.)

**SURINAM:** see GUYANA, DUTCH.

**SURVEYING** (see 26:142).—As a result of the stationary character of the World War on the Western Front, surveying generally acquired a greatly increased importance from a military point of view, and the introduction of air photography (see AERIAL SURVEY) has given the surveyor a new and powerful method for use in official circumstances. In exploratory surveying the conditions have been simplified by the introduction of wireless telegraphy, for the determination of longitude, which is now little more difficult than taking a latitude. In the more regular branches of the subject the principal matter demanding attention is the development of accurate methods of levelling, particularly of precise or geodetic levelling.

## I. SURVEYING IN WAR TIME

Topographical surveys have long been well known adjuncts to military operations. All other classes of land surveying, *i. e.*, geodetic triangulation, levelling and large scale surveying, now take their part in modern scientific warfare.

*The Trigonometrical Control.*—The extent of the Western Front made it necessary to provide a homogeneous and complete system of triangulation upon which to base the maps and the local surveys called for. Five separate and distinct triangulations already covered this area before the outbreak of war, and many of the stations of the triangulations had been destroyed or built over before the war and many were destroyed during its progress. Numbers of new stations had, therefore, to be established. This patched and reconstructed triangulation stood then as a basis for all the military surveys of the Western Front.

*Provision of Maps.*—A map of accuracy and adequate scale was required so that administrative arrangements, lines of fire and trench systems could be shown upon it. Such a map did not exist except in the Belgian area, and elsewhere had to be made. The earlier British war surveys were made upon the plane-

table, on a scale of 1/20,000, and were completed up to the British trench lines. By means of air-photography, and the manuscript sheets of the cadastral communal surveys, reliable maps of territory in British occupation and of all that portion of northeastern France occupied by the German armies were eventually compiled. The trench zone was mapped on a scale of 1/10,000, and forward and back areas at 1/20,000. In all 6,000 sq. m. were surveyed.

For the use of large scale maps in trench warfare it must be possible to read off, at sight, the co-ordinates of any desired point from a "grid" or network of lines printed on the map. For ease and accuracy of reference the "grid" should be in squares, the sides of which can be divided decimally by eye. The artillery often desire co-ordinates of the same accuracy as the surveyor, *i. e.*, on the scale of nature. The system adopted should, therefore, be based upon the co-ordinates used by the surveyor, with an easy form of abbreviation to be used by all arms to define map positions. Accuracy of bearing from any one position must be maintained together with as near an approach to linear accuracy as possible, whilst the system must allow of extension over the whole area of operations. An orthomorphic projection was, therefore desirable, and for the conduct of surveys constantly in progress it was equally important. Computations must be cut down to the minimum. This can be done by working on a projection in which the position on the ground and the position on the map can be calculated in one process without sensible error.

*Surveys for Artillery Purposes.*—Other things being equal, that artillery will dominate its adversary which has the quickest and most accurate knowledge of hostile battery positions and which can open most quickly an accurate and unexpected fire upon them. The accurate survey of the relative positions of gun and target is essential.

The positions of British heavy batteries were, therefore, fixed with a theodolite, each battery was supplied with a chart or "artillery board" on which the map was pasted down, in sections, upon a zinc or three-ply wood surface, and special "bearing pickets" were inserted in numbers in the battery zone. The bearings from these pickets to surrounding objects, suitable as reference objects, were tabulated and distributed. The positions of hostile batteries were also surveyed with as much dispatch and accuracy as possible by one or other, or both, of the following methods:—

(a) Intersection of three or more rays observed upon the flash of discharge, the reflection in the sky of this flash, or, upon the smoke puff from the muzzle, an operation, commonly known as flash spotting, which, independent of the map, gave very good results but depended for success upon good visibility.

(b) Sound-ranging (*q. v.*)—a method which is naturally unaffected by bad visibility, but is put out of action by a moderate wind blowing from base to gun and is interfered with by any high wind. As in the case of flash spotting, a good telephone connection to the artillery headquarters is essential.

## II. SURVEYING BY AIR-PHOTOGRAPHY

*Optical Principles.*—Provided that the optical axis of the camera is vertical at the moment of exposure, the resulting photograph of a flat level area will be an accurate plan at a scale determined by the equation:

$$\frac{f}{h} = s$$

where *f* is the focal length, *h* is the height of the camera above the ground at the moment of exposure, *s* is the representative fraction of the scale. Such photographs will be called vertical photographs. As a rule, however, the photograph is not exactly vertical, but the axis is tilted at an angle to the vertical. The photograph then becomes an inclined perspective view (see fig. 1.)

If the direction and magnitude of the tilt of the axis were recorded at the moment of exposure it is obvious that the photograph could be projected optically or photographically on to the plane of the map, although it would remain unfixed in position and orientation. If the direction and magnitude of tilt are unknown, then the projection on to the required plane, or

"rectification," is secured by comparing the relative positions of four surveyed points on the ground and on the photograph, which is then also fixed in position and orientation. Two matters of importance are that (1) straight lines upon a plane remain straight lines upon any perspective view of that plane; (2) at any point, on any incline perspective view, the scale is not the same in directions parallel to and perpendicular to the axis of tilt.

**Construction of the Map.**—In order to explain how a map is built up, wholly or partly, from air-photographs it is advisable to take some illustrative cases. The simplest case is that in which it is desired to produce a map of an area in which a sufficient trigonometrical control already exists and of which there is available a complete collection of cadastral plans, which are, however, much out of date. Ground features are low and gently undulating, extreme difference of altitudes being two or three hundred feet only. In such a case topography can be brought up to date from air-photographs taken with the axis nearly vertical as possible, and fitted upon the cadastral framework by one or other of the methods described below. When this is complete the map is contoured in the field, names are added and the topography examined for omissions or mistakes. The most difficult case arises when the area to be mapped is rugged and mountainous, and the inhabitants hostile: the positions and

In broken and hilly country differences of altitude must be taken into account. The use of each photograph is thus limited to the measurement of horizontal and vertical angles and to fixing the positions of new points by intersections from two or more photographs. Where this principle is employed oblique photographs are preferred as covering larger area and allowing greater refinement in the measurement of vertical angles.

Where the area to be mapped contains a sufficiently close control the filling in of topographical detail is more easily done from vertical than from oblique photographs, providing that the area in question is not markedly hilly. The scale on which photographs are taken may be larger or smaller than that of the map, but it must be sufficiently large to allow of clear identification of detail. The area to be mapped is photographed from a pre-arranged height in strips allowing for an overlap in all directions. Much depends upon the training of the pilot in maintaining his height and his overlap. It is usual to arrange for a mechani-

FIG. 2.—Diagram illustrating the graphic method of transferring detail from photo to map.

FIG. 1.—Diagram showing how an air-photograph becomes an inclined perspective view.

heights of a few peaks in it, visible from accessible ground, have been fixed trigonometrically, but no reliable map exists.

As a preliminary measure, oblique photographs are taken in the air from a variety of points of view. The positions of the camera in space are calculated, and from measurements on each photograph a number of rays are drawn to noteworthy points in the valleys and on the hills. Positions and heights are thus determined for a subsidiary control. With the axis vertical a series of photographs of valleys and of watersheds are taken, pasted together and fitted to the control. When the map has been thus built up, form-lines are added from the oblique photographs, based upon the fixed heights. In most air-photo surveys difficulties will be intermediate between the foregoing two cases.

**Applications of Air-photography.**—In any particular survey air-photographs may be used, then, for any or all of the following processes, viz.: (1) Air-photo control, (2) Air-photo topography, (3) Air-photo contouring.

In taking vertical photographs for air-photo control in fairly flat country, exposures are so regulated as to ensure a substantial overlap, generally amounting to 50% at least. Each successive photograph may therefore be fitted to its predecessor, and lines or traverses of photographs may be mounted and sealed between fixed points. Any two or more traverses of different and independent lines may be made to intersect over some topographical object, the position of which may be determined as the simple or weighted mean of the individual positions from each traverse. Traverses may also be made to converge and end upon some pre-arranged and hitherto unfixed object. This method has given fairly accurate results in flat country on the scale of 1/40,000, and is dependent upon the ability of the pilot to maintain an even keel and a constant height.

cal control of exposures regulated according to the ground speed of the aeroplane.

**Detail Plotting.**—The plotting of detail from air photographs would be simple if the axis of the camera could be maintained in a vertical position. It would then be necessary only to bring the photograph to the scale of the map. No means of ensuring this verticality has, as yet, been evolved. It often becomes necessary, therefore, to fit photographs individually upon the control points. This can be done graphically or optically by the *camera lucida*, or by the enlarging camera.

(1) The graphic method depends upon the principle that as straight lines on one plane remain straight lines on any perspective of that plane the position of a point which lies upon the intersection of two lines common to the ground and to the photograph may be readily determined. Within narrow limits the proportional compass set to the difference of scale between map and photograph at this point may be used to fix additional points. It is more accurate, however, to maintain the straight line principle and to cover the map and photograph with a "grid" of corresponding lines, as in fig. 2.

The photograph is mounted on a sheet of paper; a, b, c, d, and A, B, C, D are four points the positions of which are known and are also identifiable on the photograph. Subsidiary common points at oO are established by drawing the diagonals, and four subsidiary quadrilaterals may then be formed by drawing lines through oO from vV and wW—the intersections of the prolonged sides of the quadrilaterals. The same principle may be applied to any polygons formed by joining up any number of points (more than four) which are fixed on the ground and are identifiable on the photograph. Detail to any extent desired may be sketched in by eye.

A useful method of plotting, known as the four-point method, is as follows (fig. 3): Since the cross ratios of four points which lie upon a straight line are the same upon any perspective view of that line, we can readily plot the positions of a fifth point (S) if we know the positions of four points A, B, C, D.

Let A, B, C, D, be four known points on the photograph and a, b, c, d their positions on the map, and let S be a point on the photograph, the position of which on the map is to be found.

Join AB, AC, AS and AD, ab, ac and ad. Lay a piece of paper with a straight edge, in any position cutting the lines AB in B', AC in C' AS in S' in AD in D' and mark these cutting points on the paper. Now lay the paper strip on the map and fit it upon the lines ab, ac and ad, so that B', C' and D' lie upon these lines. Mark on the map the position of a point s' opposite the mark S' on the paper strip. Join as'. Then s, the position of point S, upon the map, lies upon the line as'. Repeat this proceeding from B, C or D, and another line bs', cs' or ds', will be secured, the intersection of which with as' will define the position of s. (2) The camera lucida (see 5.104) has been used extensively for plotting. (3) Graphic and optical methods are tedious and lengthy compared with a *photographic rectification*. The ordinary enlarging camera can be made to answer the purpose with little modification. A coincidence can be obtained between the four control points on the map and on the photograph, and a "rectified" print may be obtained.

**Ground Photographic Surveying.**—Assuming that a photograph is a true perspective view, that the plate was vertical when exposed, and that the horizon line and focal length of the lens are known, it is clearly possible to determine the horizontal and vertical angles, from the point where the camera was set up, to all objects represented in the photograph, the horizontal angles

distance for seeing, we shall clearly get a very much magnified stereoscopic effect, as compared with what is obtainable with the unaided eyes. In the diaphragm of each eyepiece let there be a similar movable mark, or line on glass. On looking through the eyepieces the marks in question will appear as a single mark floating in space, and by vertical and horizontal adjustments this mark can be made to appear to touch any given object in the picture. We have, thus, a means of measuring small parallaxes and vertical angles, and these can be read off graduated micrometer heads.

A stereo-comparator as above described gives angles from the centre of the plate, distances and vertical angles; but the reading is laborious and the map has to be constructed point by point. In 1907 and 1911 Lieutenant von Orel, of Vienna, devised a stereo-autograph which permitted the automatic drawing of detail and contours. The latest machine of the class is the stereo-cartograph of Mr. Henry Wild, made at Heerbrugg, in Switzerland, in 1925. It promises well, but all these machines are very expensive.

Generally with stereo-photography we are not limited to a country with marked features, as is the case with normal photography. Provided that the view is clear, gently undulating, or flat, country can be as well surveyed and contoured as a mountainous region. The method has some obvious applications, but it is difficult in forest-clad country or in towns and its value largely depends upon good view points. The old photographic surveying has as its chief field of usefulness a well-marked mountainous region. The new is not so limited but its rôle has not yet been fully determined.

Stereo-photo surveying, sometimes called stereo-photo grammetry, is to be seriously reckoned with in the future. Companies have been formed for the exploitation of this method in France, Germany, Spain and elsewhere. It is not only possible to make maps in this way, but also to construct plans and sections of existing buildings, and very successful results of this kind have been obtained, especially in Germany. A good account of the progress of the system will be found in "La Estereofotogrametria in 1924" by J. M. Torroja, Madrid. There is a large literature on the subject.

### III. LEVELLING

Since 1910 much progress has been made in the development of a sound system of levelling, especially with regard to precise, or geodetic levelling, which provides the framework on which all national levels depend. The now defunct International Geodetic Association laid down some wise rules on the subject. The admirable treatise of M. Ch. Lallemand, *Nivellement de haute Précision* marked a great advance on previous text-books; and the modern geodetic levelling instruments produced in France, the U.S.A. and Switzerland have greatly increased the accuracy of observation. The introduction, by the Ordnance Survey of the United Kingdom, of a specially devised kind of permanent bench-mark did away with a weak element in the old levelling, the instability of the ground marks.

**New Instruments.**—The prismatic astrolabe of Claude and Driencourt furnishes an instrument by which the observed local time and latitude can be determined by observations to at least three stars, using a constant altitude of about 60°. This method has been successfully employed in the Sudan and elsewhere. An attachment to an ordinary theodolite serving the same purpose, has been devised by Mr. E. A. Reeves, and has proved satisfactory. This does away with the necessity of taking out a special instrument. A very ingenious *direct-reading tachometer* has been brought out by Mr. H. H. Veffcott by which the computations required with ordinary tachometers are avoided. See *ARCHAEOLOGY; GEODESY; GEOGRAPHY*.

Hinks, *Maps and Survey* (Cambridge University Press, 1923); *Report of Air Survey Committee* (H.M. Stationery Office, London, 1923); B. M. Jones and J. C. Griffiths, *Aerial Surveying by Rapid Methods* (Cambridge University Press, 1925); E. Deville, *Photographic Surveying* (Ottawa, 1895); Royal Geographical

FIG. 3.—Four-point method of plotting.

being measured from some known represented object. If two such photographs are taken from two points of known lengths at known distance apart, we have the means of determining the distance and height of all points shown on both photographs.

It will, therefore, be necessary, in planning a ground photographic survey, to arrange for a triangulation to fix the relative positions at which the camera will be set up, and the first stage in the office work will consist in the plotting of the triangulation. A camera station need not, however, be a trigonometrical point, provided that its trigonometrical position can be measured from the photograph. To use the photograph for plotting the detail from each camera station A draw, at its correct angle, the central line of view. Along this line draw Ax, equal to the focal length of the lens; through x draw a line at right angles to Ax and plot from x the projections of the distant points, as measured on the horizon-line of the photograph. The intersection of rays from A to the points so obtained, with rays to the same objects from other stations, will give their position. A supplementary order of triangulation is usually added during the course of the field work, both to fix camera positions and to add a few bearings and vertical angles from which the photographic data may be checked. The office work takes two or three times as long as the field work and consists in plotting positions, calculating heights and drawing contours from the data measured on the developed plates.

**Stereo-photo Surveying.**—The most recent development of photographic surveying consists in the employment of the stereoscopic principle. In stereo-photo surveying two stations can be occupied on the same hill-top and their distance apart need only be some 50 to 300 feet.

In the simplest case let two vertical photographic plates be exposed from two points, say 100 ft. apart; let the plates be in the same plane and their centres on the same level. Then if these plates are put into a stereoscope provided with a system of lenses and prisms such that the eyepieces are brought to a convenient

#### IV. NAUTICAL SURVEYING

Naval hydrographic surveying has since the cessation of the World War steadily progressed in adopting the latest methods and instruments which have become available to the surveyor both on shore and afloat. It is not generally recognised, although it is a fact, that the hydrographic surveyor has to combine the work of the land surveyor with his own—in fact like the marine he is a “soldier and sailor too.” The World War resulted in various scientific inventions which benefited the surveyors and of which they have and are taking full advantage.

*Instruments.*—Theodolites in current use (1926) are 4 in., 5 in. and 6 inches. The majority of these are micrometer theodolites read to 10 seconds. The use of the theodolite for astronomical and tacheometer work is now universal. Sextants for observing, with stand and artificial horizon, however, are still supplied, and improvements in this instrument such as an endless tangent screw and electric light for night work, have been adopted. More portable folding stands with slow-motion screws for movement of the sextant in azimuth and altitude are also supplied, and in addition amalgamated troughs, consisting of gold-covered plates on which a thin film of mercury is floated, have superseded the old artificial horizon consisting of a mercury bath; the new pattern is far less sensitive to earth tremors caused by surf, traffic, etc. It is, however, recognised that this instrument for work on shore is now superseded by other more precise and compact instruments.

The astrolabe a prisme, a very precise instrument, is one of these. It is used for finding position and enables altitudes of any stars at the altitude of  $45^\circ$  or  $60^\circ$  to be observed. The latest form of astrolabe enables observations of stars to be easily and accurately made as follows with the  $60^\circ$  instrument—one step of  $7\frac{1}{2}'$  on either side of  $60^\circ$ , that is 3 observations of  $59^\circ 52\frac{1}{2}'$ ,  $60^\circ$ ,  $60^\circ 07\frac{1}{2}'$  can be taken of one star. With the  $45^\circ$  instrument—four steps of  $5'$  on either side of  $45^\circ$ , that is 11 observations of  $44^\circ 40'$ ,  $44^\circ 45'$ ,  $44^\circ 50'$ ,  $44^\circ 55'$ ,  $45^\circ$ ,  $45^\circ 05'$ ,  $45^\circ 10'$ ,  $45^\circ 15'$ ,  $45^\circ 20'$  can be taken of one star. The great advantage of this instrument is that with one setting up of the instrument and without a number of necessary readjustments as in a theodolite both time and latitude can be determined, provided of course that the best and latest method of obtaining error of the time used (*i.e.*, wireless time signals) is adopted. When it is found necessary to measure bases the hydrographic surveyor uses the 500 ft. steel measuring tape and is provided with the Kew standardisation certificate. In surveying abroad where no local triangulation exists, the accurate measurement of a base is recognised as a most important step, second only to a satisfactory base extension.

Tacheometers and tacheometer staves marked according to the Admiralty pattern are used for measuring distances up to over 2,000 ft. where extreme accuracy is not necessary. One-metre base range-finders are useful in measuring short bases for plans of harbours, etc., when time or circumstances do not permit of a more accurate method. Of the various forms of heliostat the Galton sun signal has proved a most excellent instrument and fitted to theodolites it allows of the sun's rays being quickly and accurately directed to and kept on the station desired, whether the latter is visible or not.

Taut wire measuring gear is now fitted in all British surveying ships. This method of measuring distances at sea in comparatively shallow depths had proved most successful and was adopted after having been extensively used in connection with mine-laying during the War. The ship preserves a steady course and at a constant speed over the distance to be measured and at the same time runs out a thin piano wire from a drum which carries many miles of the wire. It is laid taut by means of a special brake device, the amount of wire out being registered on a dial. A correction (always subtractive) must be made for errors. This varies from 1,000 to 3,000 ft. in a distance of 100 m., and is governed by the contours of the sea bed upon which the

wire has been laid. The dial registers 1,000 rev. for a mile of 6,080 ft.; consequently when plotting in sea miles a second correction, for latitude, is necessary. This method of determining distance is specially useful when surveying out of sight of land, and is used in combination with astronomical observations and moored beacons.

*Fixing Positions of Ships, Buoys, etc., by Subaqueous Sound-ranging.*—This new method of accurately fixing the positions of buoys, etc., is carried out by dropping an explosive charge at the position it is required to fix. The sound of the explosion travels through the water to a number of hydrophones suitably placed, and the positions of which are accurately known. The differences between the times at which the shock reaches the various hydrophones are recorded photographically by a galvanometer on shore, to which the instruments are connected by cables. From these observations it is possible to calculate a position line for each pair of hydrophones. Three or four such lines from hydrophones suitably placed will give a cut, which is the position of the explosion. As in all surveying problems, the accurate fixing of a point from two others depends on the length of the base, that is, the distance between two known points, so does the accurate fixing by sound through the water depend on the hydrophones, or groups of hydrophones being such a distance apart, commensurate with the distance at which it is required to fix the buoy, etc.

*Chronometers.*—Surveying ships are now supplied with from 8 to 12 chronometers of the box type (pocket chronometers being used outside the chronometer room) selected instruments which have successfully passed most exhaustive tests at the Royal Observatory, Greenwich. For astronomical work on shore, the portable “Lindqvist chronograph” is employed. In this instrument, a chronometer fitted with special contact pieces automatically sends an electric current every two seconds through an electro-magnetic coil, and thus, by suitable mechanism records every alternate second as a perforation on a paper tape, which is kept moving at a uniform rate by means of clockwork. The closing of a switch by the observer operates a second coil, which records the instant of observation in a similar manner by making an additional perforation in the tape.

Wireless telegraphy for accurate time and obtaining meridian distances has been adopted. Amongst minor improvements in surveying appliances may be mentioned the standardisation of the markings of leadlines, improved buoys for beacon work, light filters for fitting to the eyepieces of sextant and theodolite telescopes.

In 1926 electrical lighting arrangements to sextants and theodolites had greatly improved. The arcless sextant which enables angles to be taken and read off (on a drum) without the necessity of removing the eye from the telescope; wireless telegraphy outfits for use of detached parties and the gyro compass (*see* GYROSCOPES), were all in use. For the measurement of velocity of tidal streams and current the Ekman current meter was generally in use.

In calculating triangulations, considerable time is saved in correcting for false station by use of the station corrector diagram, by which the correction can be obtained very quickly to any accuracy required (generally about 5 sec. of arc) and the tedious trigonometrical calculation avoided. The slide rule has come far more into prominence for small rough calculations. As the result of modern inventions, special charts for the use of submarines and for other purposes in addition to the ordinary navigational chart have been produced. Charts for submarines indicate graphically the nature of the sea bottom, so as to indicate where vessels can rest with safety.

The introduction of wireless direction-finding stations as an aid to navigation has necessitated the production of charts drawn on the gnomonic projection, by the use of which positions can be more accurately determined. Additional charts are also required for testing range-finders and compass adjusting. Physical charts indicate the direction of prevailing winds and ocean surface currents at different periods of the year, localities and time where ice may be fallen in with, and the direction and

force of the stream and drift currents of the oceans. Considerable gain in accuracy and prevention of distortion has been obtained by printing charts by lithography, although the original charts are generally speaking engraved on copper. No more marked advance has been made in hydrographic surveying than in that most important work of all, viz.: ship and boat sounding; and reference should be made to the article on that subject (see SOUNDING).

(See John Ball and H. Knox Shaw, *A Handbook of the Prismatic Astrolabe*, Egyptian Govt., Cairo Government Press (1919); C. F. Close, *Text Book of Topographical Surveying* (1925).

#### SURVIVAL: see PSYCHICAL RESEARCH.

**SUTTNER, BERTHA**, BARONESS VON (1843-1914), Austrian writer (see 26.171), died at Vienna June 21 1914. See H. v. der Mandere, *Bertha Suttner* (1909).

**ŠVABINSKÝ, MAX** (1873- ), Czech painter, was born at Kroměříž in Moravia. He studied at the academy of fine arts in Prague, where he eventually became a professor; and in Paris, Germany, Holland and Belgium. His first works were made to suit the poetical and symbolic mood prevalent at the time, but he soon turned his attention to realistic subjects, from which he derived the sources of an art intoxicated with the manifestations of life and nature. There is hardly any branch of painting which Švabinský did not practice with success. Of his large-sized canvases, special reference should be made to "The Sun Bath" (1908), "Summer" (1909), and "The Family in the Mountains," which provide typical examples of the vivid manner in which the artist seizes upon colour and form. As a portrait painter and etcher, Švabinský was remarkably active, his subjects including such prominent representatives of Czech public life as Mánes, Smetana and President Masaryk, while by his portrait of Maeterlinck he gained much appreciation abroad. Among his numerous other works should be mentioned the cycle of woodcuts entitled "The Sonata of Paradise" (1918-20).

**SVEHLA, ANTONIN** (1873- ), Czech statesman, was born at Hostivař, near Prague. From his youth he devoted himself to the movement for the emancipation of the Czech agricultural classes, rendering considerable services in founding and developing the Czech Agrarian party, of which in 1909 he became chairman, and which from 1908 he represented in the Provincial Diet of Bohemia. During the World War he played a most important part in Czech political life, bringing about the unity of all classes of the population and maintaining an undivided national front at the period of the greatest persecution. Contact with Professor Masaryk and those who worked with him abroad on behalf of Czechoslovak independence enabled him to complete the preparations for the final coup against Austria on Oct. 28 1918, when in his capacity as vice-president of the Prague National Committee, together with Dr. Soukup and J. Stříbrný, he took over the Government of the Czechoslovak State on behalf of the Czechoslovak National Council; which in the summer of 1918 had been recognised as the Czechoslovak Provisional Government. He became a member of the first National Assembly and was Minister for the Interior until Oct. 1922, when he undertook the formation of a new Czechoslovak coalition Govt. which he reconstituted after the Oct. 1925 elections. During his period of premiership he displayed admirable political and diplomatic abilities, notably by his skilful handling of the differences between the political parties.

**SVENDSEN, JOHANN SEVERIN** (1840-1911), Norwegian composer (see 26.175), died at Copenhagen June 14 1911.

**SWAN, SIR JOSEPH WILSON** (1828-1914), British physicist (see 26.179), died at Warrington, Surrey, May 28 1914.

**SWANSEA, WALES** (see 26.181), the most important port of shipment in Great Britain for tin plates, patent fuel, etc., and the chief centre of the anthracite, spelter and copper trades, had a population of 157,554 in 1921, and an area of 21,600 acres. Oystermouth and a large part of the Swansea rural district were included in the borough in 1918. There are many manufactures, especially those concerned with metal working. A new dry dock was opened in 1924 in the harbour, which has 281 ac. of deep

water in the docks, and over 6 m. of quays. Among the newer buildings are the Glynn Vivian art gallery in Alexandra road (1915); the large Dockers' Hall in High street (1913); the Y.M.C.A. centre in St. Helen's road (1913) and the chamber of commerce buildings (1915). In 1920 the technical college was made a constituent college of the University of Wales. Singleton House, with a park of 300 ac., presented to the municipality, is occupied by the college, pending the completion of new buildings in the park, of which the foundation stone was laid in 1920. Since the World War Swansea has become a centre for the distribution of oil, and extensive facilities for its storage and refining have been provided, tanks, refineries, pipe lines, etc. having been erected.

**SWAZILAND**, a British protectorate in South Africa (see 26.184). The population in 1921 was 133,563, of whom 2,203 were whites. The native population had increased by 5.34% since 1911. The state of chaos into which Swaziland had fallen owing to the indiscriminate grant of concessions was ended by 1914. Out of a total area of 4,275,000 ac., 1,635,000 ac. became Swazi reserves; in addition the Swazis bought 77,000 acres. A law suit arising out of these concessions led to a decision being given by the judicial committee of the Privy Council, in April 1926, that the crown had acquired sovereign rights in the disposal of the land of the protectorate—a right which the Swazis had challenged.

The Swazis own large herds of cattle and grow maize and other crops. Some 7,000 to 8,000 Swazis find employment in the Rand gold mines. The whites are mainly farmers. Gold mining has been practically abandoned. The maximum output was 14,781 oz. in 1911-2; in 1924 the output was 376 ounces. The coal deposits have not been worked. Tin (cassiterite) is found on the western border; the export varies from 200 to 400 tons a year; the total value of tin produced in 1915-24 was £510,000. From 1921 onward cotton growing was developed; in 1924 the value of cotton exported was over £10,000. The chief exports are slaughter oxen and tin. Revenue and expenditure balance closely. Revenue rose from £49,000 in 1911-2 to £89,000 in 1924-5, and expenditure in the same period from £45,000 to £87,000.

The administration is under the charge of a resident commissioner, with headquarters at Mbabane, a small, picturesquely situated hill village (altitude 4,000 ft.) overlooking the middle veld. The paramount chief and other chiefs exercise jurisdiction in all civil cases in which natives only are concerned. Labotsibeni, otherwise Naba Tsibeni, the "queen regent," a well-known figure in Swazi history, acted for many years as paramount chief, first after the death of her husband Mbandini in 1889, and later after the death of her son, Bhunu; her grandson, Sobhuza II., was installed as paramount chief in 1921. Labotsibeni died in Dec. 1925. Education is mainly in the hands of missionaries; Sobhuza was educated at a Government school at Labotsibeni's kraal, and afterwards at the missionary establishment at Lovedale. Like many other Swazis he adopted European clothing. Mr. de S. M. G. Honey, who had served in Swaziland since 1904, became in 1917 resident commissioner, and still held that office in 1926. In 1921 he set up an elected European advisory council to deal with purely European affairs.

The development of Swaziland, favourably situated midway between Delagoa Bay and the principal markets of the Transvaal, and itself potentially a very rich country, was greatly retarded by the lack of railways and good roads, for the building of which funds were not forthcoming. A railway built by the Portuguese from Delagoa Bay stopped at a dead end at the Swazi border. Continued through Swaziland, it would afford the shortest route to the Rand. Swaziland being under direct British administration, the South African Govt. gave no facilities for the building of the railway. Its construction was regarded as dependent upon Swaziland joining the Union. When the question of incorporation was raised definitely in 1924, it appeared that the white settlers were not willing to become part of the Transvaal province, but that if Swaziland were incorporated in the Union, it should be as a separate entity. The chief event in the Protectorate in 1925 was the visit of the Prince of Wales.

See *Official Year Book of the Union of South Africa* (Pretoria, 1925), the annual *Report on the Protectorate* issued by the Colonial Office, London, and *The Times*, April 16 1926, *Sobhuza II. v. Miller* (Privy Council Judgment).

**SWEDEN** (see 26.188), a kingdom of northern Europe and a member of the League of Nations. Its area is 173,105 sq. m. and the population (1924) 6,036,118.

### I. POLITICAL HISTORY

On the death of King Oscar, Dec. 8 1907, his son became King of Sweden with the title Gustav V. After the dissolution of the union with Norway, sweeping reforms were introduced by the Liberal Ministry under Karl Staaff (1905-6) and the Conservative Ministry under Lindman (1906-11). The main problems were the extension of the political and municipal franchise and the adjustment of national defence. The franchise was reformed (1907-9), and the first elections for the Second Chamber under the new conditions took place in Sept. 1911. In 1905, the electorate numbered 402,000; in 1911, 1,066,000. The result of the election favoured the Left wing, and Karl Staaff formed his second Liberal Ministry, which in 1913, with the help of the other political parties, passed a law for national pensions insurance. The international unrest necessitated a complete overhauling of the national defence. The Staaff Ministry instituted a thorough investigation, and intended introducing a Government measure during the 1914 Riksdag.

At that time public opinion was much exercised over the military activities of Russia in Finland, which it was thought constituted a menace to Sweden. Staaff outlined his policy at the end of 1913 in a public speech, from which it appeared that the main question—the increase of the training period for the infantry—would be deferred until after elections to the Second Chamber in the autumn of 1914; the other items, however, were to be submitted to the 1914 Riksdag. These delays aroused much public feeling and in Feb. 1914, 30,000 peasants assembled in Stockholm to request the King that the whole question of national defence should be handled simultaneously. The King's answer was favourable, and this led to a conflict between himself and the Liberal Ministry, which resigned. The King commanded the *landshövding* Herr Hjalmar Hammarskjöld (*q.v.*) to form a new ministry. Herr Karl A. Wallenberg became Minister of Foreign Affairs. The Second Chamber was dissolved and the Riksdag reassembled after the election of May 1 1914. The supporters of the new Government won some seats but had no majority in the Second Chamber. In the First Chamber, however, they had a friendly majority.

**National Defence.**—Before the question of national defence could be handled the World War broke out. With the help of the Liberal party, the problem was solved by increasing the training period for recruits (in the infantry to 340 days followed by the usual annual training courses; for the other arms the increases were in some cases rather less, in others rather more). The system of maritime fortifications was strengthened and large grants were made for the fleet and for the provision of war materials. To meet the extraordinary expenditure a war tax was levied on all incomes above a certain amount. It was widely, but quite erroneously, believed that Sweden had entered into a treaty with Germany. Sweden immediately issued a declaration of complete neutrality, which she maintained strictly. Military patrols were stationed at all the more important points of communication and at certain points along the coast. The fleet endeavoured to prevent any military operations within Swedish territorial waters. Breaches of neutrality occurred, however, entailing complaints and sometimes apologies and compensation.

**The Difficulty of Neutrality.**—The difficulties of western trade over the North Sea increased. Many Swedish vessels were destroyed, with great loss of life, by German submarines and by mines laid by both belligerent groups. As the blockade against Germany was intensified, an increasing amount of Swedish goods were detained in England. The black lists of the belligerents, trade espionage and the attempt to force extensive

undertakings from importers in neutral countries induced the Swedish Govt. to put a proposal for a War Trade Law before the 1916 Riksdag, under which no undertakings with belligerent Powers could be made without the sanction of the official Swedish authority (Trade Commission). If this officially recognised undertaking were broken the culprit was severely punished. Special arrangements were made with the belligerent countries regarding compensation for permission to transport goods. Britain desired to transport over Sweden goods necessary to Russia, and Sweden granted a transport licence in return for permission from Britain to import certain foodstuffs from the west. In Jan. 1915 the Government forbade the transport over Sweden of arms and other war material. Pourparlers between the Swedish and British governments with the object of improving trade communications between the two countries led to no result. Disputes arose over the British postal censorship and the closing by Sweden of a channel in Öresund. These difficulties brought the three Scandinavian countries into closer touch. In Dec. 1914, King Gustav invited the kings of Norway and Denmark to a conference in Malmö which inaugurated a period of greater friendship between the three countries.

**Special War Legislation.**—Many legal and administrative innovations were made. In 1914 a moratorium for debts was introduced, but was soon abolished. Special laws empowered the Government to fix a maximum price for food and other necessities and if necessary to commandeer them. The Government also exercised a certain control over the merchant service. A War Insurance Commission was set up to give state-aided insurance against loss at sea, a Food Commission to take over the import of grain, etc., an Industry Commission to report on industry and later to ration raw materials, etc., an Unemployment Commission, and a Trade Commission to carry out the war trade laws. In Nov. 1915 the first maximum prices were fixed (for grain). A bad fodder harvest and the difficulty of importing maize and other foodstuffs necessitated a great slaughter and export of cattle. The War caused a lull in internal party strife during 1915, but in the following year lively discussions took place as to how Sweden could best maintain her policy of neutrality. Some circles sympathised with Britain, others with Germany, but most desired neutrality. A little group of "activists" urged intervention on the side of Germany, but all political parties held aloof from them.

**Pressure of the Blockade.**—On July 7 1916 Britain and France ceased to apply the regulations of the Declaration of London regarding neutral trade. The difficulties already attending neutral trade were now multiplied. The German U-boat warfare was intensified; the closed areas in the North Sea and the blockade of the Central Powers by the Allies created a situation little in accord with the pre-war regulations concerning international law. The Premier, Herr Hammarskjöld, championed the preservation of international rights in the name of the Swedish Government. He met with small success, even although the three Scandinavian kingdoms combined in the protest. During the War 280 Swedish merchant vessels were sunk, chiefly by German submarines, but also by mines and from other causes. The English ports were crowded with confiscated goods. After the Russian revolution in 1917, Britain no longer needed to transport goods over Sweden to Russia, so this means of exchange fell away.

Negotiations with Britain for import licences led in the spring of 1917 to a temporary agreement whereby Sweden was guaranteed certain imports (including grain) in return for the release from the Baltic of a number of imprisoned vessels belonging to the Entente. The tonnage question played an important rôle in Entente policy, and Swedish vessels were requisitioned or were only allowed to sail in Swedish interests on condition that they were replaced by other vessels when required. Finally a commercial agreement was concluded in the spring of 1918, which enabled Sweden to import large consignments of goods in return for handing over merchant vessels up to 400,000 tons dead weight; a certain proportion of the Swedish iron ore export; longer credit for goods purchased in Sweden, and stricter

regulations regarding exports to Germany. The increasing difficulties of navigation in the North Sea and the insignificant export from Britain to Sweden, led to an expansion of trade with Germany. Before the War Sweden obtained 91% of her coal from England but during 1916-7 only 27-26%. The remainder was almost entirely supplied by Germany. The dislocation of trade thus largely influenced Sweden's policy, as in all her undertakings and agreements with the Entente Powers she had to reserve a considerable amount of commodities for exchange with Germany.

Import difficulties necessitated still more stringent state measures. In Oct. 1916 sugar was rationed. In 1917 bread cards were introduced together with State control of the whole grain trade. Before the War an average of 183 kilogrammes of wheat and rye were consumed per head. The harvest of 1917-8 produced only 84.4 kilogrammes per head. Finally, potatoes and many other commodities were rationed. There was a great shortage of meat and bacon, and milk was reserved for children and invalids. The price of food rose rapidly and large sums of money were set aside to provide the poorer classes with goods at cheap rates. As the import of coal decreased, special arrangements were made for procuring wood from the forests. All kinds of raw materials, especially lubricants, were scarce. The Hammarskjöld Ministry was formed against the wishes of the Liberals and the Social Democrats, and these parties commanded a majority in the Second Chamber of the Riksdag.

*Changes of Government.*—The Government only remained in power so long thanks to its firm neutral policy. Criticism of its trade policy increased, however, and in spite of a huge vote of confidence from 750,000 people, it was unable to co-operate further with the parties of the Left and resigned at the end of March 1917. A new Conservative Ministry carried on up to the new elections to the Second Chamber in the autumn. Herr Karl Swartz, a manufacturer, was Prime Minister and Adml. Arvid Lindman, a former Prime Minister, was Minister of Foreign Affairs. The food shortage caused considerable unrest and led to a demand for a constitutional reform of a democratic nature. At the autumn elections the Conservatives suffered several losses and Herr Swartz resigned. In view of the abnormal conditions, the King endeavoured to bring about a coalition government of all parties, but he was not successful and the Liberal leader, Prof. Nils Edén, formed a Ministry. He himself became Prime Minister and Lord Justice Johannes Hellnér, Minister of Foreign Affairs. The Ministry included five other Liberals and four Social Democrats. Among them were Herr Hjalmar Branting as Minister of Finance, and Baron E. Palmstierna, afterwards Swedish minister to London, as Minister of Marine. Branting soon resigned on account of illness. The main items in the programme of the new ministry were a great constitutional reform and a trade agreement with the Allies (*see above*). The Government motion on the question of constitutional reform was thrown out by the First Chamber during the 1918 Riksdag; but a law was passed instituting great educational and Poor Law reforms.

*Finland and the Aaland Is.*—In Jan. 1918, Sweden recognised Finland as an independent State. The Civil War in Finland created a critical situation. There was a demand for military support of the lawful Finnish Govt.; yet Sweden feared she might be drawn into the War if she assisted the Finns against the Russians and appeared to side with the Germans, to whom the Finnish Govt. had appealed for assistance. The Government acted with a circumspection which was rather resented by the Finnish middle classes. When the conflict was transferred to Aaland and its inhabitants voted for adherence to Sweden, Sweden sent a warship to the islands, and a small body of troops to maintain peace. These were, however, recalled when the Germans made the islands their centre for sending assistance to the "Whites" in Finland (*see AALAND ISLANDS*).

*Swedish Relief Work in belligerent Countries.*—The Swedish Red Cross was active in the adjacent belligerent countries, and Prince Carl, a brother of the King, took a prominent part in the work. Swedish delegates inspected the prison camps of Russia,

Germany and Austria and distributed numerous gifts to the prisoners from their respective countries. Arrangements were made for the exchange of invalided prisoners and their transport over Sweden. After the War large numbers of German and Austrian children spent some time in Sweden renewing their health and strength, and Swedish help was given to the impoverished countries. When the great famine broke out in Russia a Swedish relief expedition was sent to Samara. The sum total of relief given by Sweden to the various countries amounted to 36,500,000 kroner.

*Internal Conditions after the War.*—The repercussions of the revolution in Central Europe reached Sweden. The Riksdag was sitting when the War ended and in order to keep in power, the Government hastened to put forward a programme embodying a far-reaching constitutional reform, which was carried, thanks to the close co-operation of the government parties. The graduated scale at the communal elections was abolished and equal and universal suffrage introduced. As the First Chamber is based on the communal vote, it became automatically more democratic. Women received full political franchise. The Social Democratic party consequently acquired a relative but not an absolute majority in each Chamber. Dissensions among the middle-class parties—the Conservative, Liberal and the new Bondeförbund (Farmers' League)—further increased the power of the Social Democrats; but lacking an absolute majority, they were obliged to act rather as a Radical middle-class party. The Edén Ministry remained in office until March 1920. The liquidation of war-time restrictions and the work of reform continued. A provisional law adopting an eight-hour day in industry and certain other branches of labour, not including agriculture, was passed. The Liberal and Social Democratic members of the Government disagreed on the reform of communal taxation, and the Ministry resigned after it had first laid before the Riksdag a proposal for Sweden's entry into the League of Nations.

Branting now formed his first purely Social Democratic Ministry with Palmstierna as Minister of Foreign Affairs. This ministry set on foot investigations into projects of socialisation, industrial democracy and control over trusts and cartels. At the Second Chamber elections the Conservatives and the *Bondeförbund* gained several seats; Branting therefore dissolved his Ministry on Oct. 22 1920. Baron Louis de Geer formed a moderate Conservative ministry, at the head of which Herr Oscar von Sydow replaced him in Feb. 1921. The Government granted large sums for relief work and the support of the unemployed. To carry out the new constitutional reforms fresh elections for both Chambers took place in the autumn.

*Unemployment.*—The result favoured the Socialists, especially in the First Chamber and in Oct. Branting formed his second purely Social Democrat Ministry, in which he himself was both Premier and Minister of Foreign Affairs. The economic crisis and the problem of unemployment were the vital questions at the moment, and at the instance of the Government the 1922 Riksdag granted what were, according to Swedish ideas, enormous sums of money for the relief of the unemployed. The Government finally fell over this question of unemployment. Swedish policy was to provide relief work whenever possible, otherwise to give monetary assistance. Wages for relief work were to be less than ordinary wages and assistance still less. Help was not to be given to workers involved in any conflict (strike or lock-out). The Government and the Riksdag interpreted this last clause differently, and Branting resigned in April 1923. During 1922 a referendum on the total prohibition of all alcoholic drinks was defeated.

*Controversy on Defence.*—Lord Justice Ernest Trygger, the old Conservative leader, now formed a new Ministry, whose special task was the solution of the national defence question. The 1914 army regulations had not been entirely carried out when the War ended and the Socialists, especially, felt strongly that the creation of the League of Nations and the fall of the Tsardom justified a reduction of armaments. During the 1924 Riksdag the Government had brought in a bill for this purpose,

but it was not sufficiently drastic for the Social Democrats and the *folkfrimnade* (the Radical half of the old Liberal party; the rest still called themselves Liberals). The Riksdag threw out the bill, but the Government remained in office until after the Second Chamber elections in September. As the result did not strengthen the Government, it went out, and Branting formed his third Ministry on Oct. 18 1924, with Prof. Östen Undén as Minister of Foreign Affairs. The Government and the Social Democratic party suffered a severe loss in the death of Branting (q.v.) on Feb. 24 1925. Rickard Sandler, Minister of Commerce, succeeded him as Prime Minister. A Government measure, introducing shorter military service and a reduction of the army, was passed by the 1925 Riksdag.

**Foreign Affairs.**—When the question of the entry of Sweden into the League of Nations was broached there was considerable opposition, one reason being the non-entry of the United States. The decision to join was, however, carried by a large majority and in March 1920 her entry into the League was officially announced. Among the Swedish representatives at the League Assemblies were Branting, Trygger and Undén. In Sept. 1922 Sweden was given a seat on the Council.<sup>1</sup> The Åland question (q.v.) was decided by the League in favour of Finland (June 1921) but the islands received guarantees for the preservation of their Swedish culture. An international Convention prohibited any fortification of the islands.

The co-operation established between the three Scandinavian States during the War was not continued in any definite form. There was much talk of a Scandinavian Alliance, but Norway was disinclined to join it. From time to time the Foreign Ministers of Norway, Sweden, Denmark and sometimes Finland, met to discuss foreign policy. Sweden concluded a trade agreement with Russia on March 16 1924. On March 5 1924, at Sweden's invitation, delegates of the Swedish, Norwegian, Danish and Finnish governments met and unanimously adopted a draft for setting up permanent conciliation councils for compulsory arbitration of differences not previously settled by diplomatic action or through the Permanent Court of International Justice. On June 27 six bilateral conventions based on this draft were signed between the States concerned. On Jan. 25 1925 Sweden signed a treaty with Norway making all differences of all kinds subject to arbitration.

## II. ECONOMIC AND FINANCIAL HISTORY

**Population.**—The population of Sweden at the end of 1910 consisted of 5,522,403 persons. By the end of 1925 it had risen to 6,053,562, representing a yearly increase of 6.12 per 1,000. The birthrate has steadily declined from 24.66 per 1,000 in 1910 to 17.53 in 1925, the lowest return for any European country. The death-rate has, however, also declined, viz.: from 14.04 per 1,000 in 1910 to

11.72 in 1925. During the five years 1909-13 emigration rose to 2.44 per 1,000 per annum, but sank to an insignificant figure during the War. Between 1921 and 1925 it again rose to 1.36 per 1,000 per annum. In 1910, 24.8% of the whole population were town dwellers. In 1924 the number had increased to 30.6%. The division of labour, according to the census of 1920, was as follows: agriculture 38.5%, industry 31.3%, trade and communications 12.9%, public services and professions (*fria yoken*) 4.6%, domestic service, retired workers, etc., etc., 12.7%.

**Pre-War Period.**—The period preceding the World War was characterised by greatly increased production and trade turn-over and by a marked growth of capital. From 1909, when trade depression reached its lowest level, to 1913 the industrial workers increased, according to statistics, from 320,000 to 360,000. The estimated value of the harvest rose from 778,000,000 kr. to 857,000,000, the total value of foreign trade from 1,087,000,000 kr. to 1,664,000,000, equivalent to 53% (imports by 38% and exports by 73%). Deposits in banks and savings banks increased from 2,207,000,000 kr. to 2,800,000,000.

### EFFECTS OF THE WORLD WAR

Although Sweden took no active part in the War, it had, nevertheless, in many respects, a profound bearing upon the economic conditions of the country. The cost of living increased enormously. The Swedish index number for wholesale prices, reckoned at 100 for the period July 1, 1913 to June 30 1914, reached, on an average, 339 in 1918. The number of bank-notes in circulation increased from 234,000,000 kr. at the end of 1913 to 814,000,000 kr. at the end of 1918. This was made possible by relieving the Riksbank from the liability to meet notes with gold. Incomes and property were naturally affected by the sudden inflation. Many new fortunes were made, but, at the same time, large numbers of well-to-do people—small investors and wage-earners were reduced to poverty.

**War Scarcity.**—The rupture of communications with foreign countries, as a result of the War, was of great import, especially as regards the maintenance of food supplies. The import of grain, which averaged 284,000 tons in 1911-3 was reduced to only 80,000 tons in 1917-8. The supplies of fodder and artificial manures almost entirely ceased, likewise the supply of fats and colonial goods. In order to exercise the greatest economy with the inadequate resources, maximum prices for agricultural produce were fixed. From the end of 1916 state rationing of sugar and wheat was introduced. Later on certain other foodstuffs, and even clothing, were rationed. The great reduction in the supplies of coal rendered necessary vigorous measures to provide home-grown wood for coal fuel, while the lack of lamp and fuel oils was supplied partly by the use of acetylene and partly by enforced development of electric power. Strenuous efforts were also made to utilise the native resources in order to replace imported raw materials necessary for industry.

Notwithstanding this, many industries, the textile in particular, were forced to limit their output owing to lack of raw materials. On the other hand, the War caused a boom in certain trades, especially in the metal industries which had access to good raw materials in the country and whose manufactures were of great use in warfare. For example, production of pig-iron rose from 640,000 tons in 1914 to 820,000 in 1917 or by nearly 30%. The shipping trade flourished exceedingly and reaped immense profits.

**Deflation.**—War conditions and the inflation of the currency led to unprecedented speculation, the extent of which may be gauged from the figures of the transactions on the Stockholm bourse (in 1913, 638,000,000; in 1918, 5,726,000 kr. on an average per Exchange day). The boom came to a hasty end with the termination of the War. Rationing ceased, and foreign goods began to pour into the country. During the years 1914-8 there was a continuous excess of exports over imports. This was now changed to a considerable excess of imports over exports. From the year 1921 a violent deflation took place. The index number of wholesale prices fell successively from 366 in June 1920 to 150 in Dec. 1923, that is to say, by nearly 60%. The consequences of this were seen in the great increase in unemployment, which

<sup>1</sup> At the extraordinary session of the Council of the League called in March 1926, to consider the German application for the admission of the Reich, M. Undén, under instructions from his Government, declared, in face of the claims put forward by other countries for permanent seats on the Council, that Sweden would not consent to any immediate additions to the Council other than that of Germany. In the dispute which followed Sweden and Czechoslovakia offered, in the interests of peace, to resign their seats to allow of the election of two other Powers to non-permanent seats. This offer failed in consequence of the attitude of Brazil towards the admission of Germany.

reached its maximum figure in Jan. 1922 when 163,000 unemployed were registered. At the same time the statistics of the trade unions showed that over 30% of their members were out of work. The wise and energetic unemployment policy pursued by the State soon succeeded in surmounting the evil and by the end of 1923 the abnormal conditions were, in the main, overcome. The Swedish exchange during the years 1916-8 rose on occasions to over 20% above par in relation to the dollar, but, during 1919-20 fell considerably below; from 1921 onwards a gradual improvement took place and by the end of 1922 the krona was brought up to par and on April 1 1924 Sweden returned definitely to the gold standard, the first European nation to do so.

#### POST-WAR CONDITIONS

**Agriculture.**—The extent of cultivated land has changed but little since 1911 (in 1911, 3,600,000 and in 1924, 3,800,000 hectares). On the other hand a certain displacement has taken place in the relation between the various crops. The harvest of different staple products for the years 1911-3 and 1923-5, reckoned in 1,000 metric tons, averaged: wheat 230 and 287 respectively, rye 596 and 527 respectively, barley and oats 1,922 and 1,899 respectively, potatoes 1,587 and 1,748 respectively, sugar beet 890 and 1,093 respectively, root fodder crops 2,693 and 2,924 respectively. The number of cattle in 1913 was 3,069,000, in 1920, 2,736,000; of sheep for the same years 1,205,000 and 1,568,000 respectively; of pigs 1,023,000 and 1,011,000 respectively. The import of wheat and rye during 1911-3 averaged 284,000 tons per annum (including flour), during 1923-5 374,000 tons. The export of butter which in 1913 amounted to about 20,000 tons (of which 16,000 were sent to England) ceased completely during the War, but in 1925 it amounted to 9,000 tons.

**Industry.**—The development of industry is best indicated by the number of workers employed; it had risen from about 360,000 in 1913 to 417,000 in 1920. The number fell to 326,000 during the trade depression of 1922 but rose again the following year to 358,000, about the same number as in 1913.

A great change-over also took place in industrial production with the result that the iron industry, one of the oldest staple industries of Sweden, became less important, while the wood trades, especially the wood pulp and paper industries, have come very much to the fore. During the years 1911-3 foreign trade showed a slight excess of imports over exports (an average of 26,000,000 kr. per annum); during 1914-8 inclusive a total excess of exports over imports for the five years of 1,345 million kr., i.e. 269 million per annum; from 1919 onwards, again an excess of imports. The most important exports were in 1925, timber (291,000,000 kr.), wood pulp (230,000,000 kr.), machines (138,000,000 kr.), paper (135,000,000 kr.), iron ore (122,000,000 kr.), iron and steel (69,000,000 kr.).

**Communications.**—The mercantile marine has been much increased; at the end of 1910 it comprised 1,047,000 tons gross weight, at the end of 1925 1,420,000, an increase of 35%. Steamship and motor-boat tonnage increased by 466,000 tons, sailing vessel tonnage decreased by 93,000 tons. The system of communications has also been much improved, the total length of the railways in 1910 was 13,829 km., in 1924, 15,710 kilometres. The number of telephones for the same years was 187,000 and 418,000 respectively, and the number of automobiles in 1919 was 8500, in 1924, 62,000.

**Banking.**—A very noteworthy process of amalgamation had taken place in the banking world. In 1910 there were 80 banks whose united capital amounted to 543,000,000 kroner. In 1925 the number had fallen to 32 with a capital of 804,000,000 kroner. The largest banks are Skandinaviska Kredit A.-B. (capital 182,000,000 kroner), Svenska Handelsbanken (capital 105,000,000 kr.), Stockholm's Enskilde Bank (capital 85,000,000 kr.), and A.-B. Göteborgs Bank (capital 79,000,000 kroner).

**Finance.**—In 1911 the state budget amounted to 243,000,000 kr., the budget year 1924-5 to 707,000,000 kroner. If the latter sum is reduced to the same money value as the former it will represent a rise of about 60% during the period and give an idea of the extent to which state activities increased during those years. The income and property taxes during the first mentioned year amounted to 14% of the whole revenue; during the latter year to 20%. The revenue derived from the customs and excise remained pretty uniform, namely 44 and 43% respectively. On the other hand that derived from state undertakings (railways, postal services, telegraphs, forests, landed property, waterfalls and the state bank "Riksbank") was reduced from 18 to 13%. The consolidated national debt at the end of 1910 amounted to 537,000,000 kr., at the end of 1925 to 1,717,000,000 kroner. A material change in its investment took place, however during the War. Until then 90% of the whole debt was placed abroad. By 1925 outstanding obligations had been redeemed, and new loans issued on the home market with the result that 80% of the total debt was in Swedish hands.

**Social Conditions.**—Since 1914 many important reforms have been carried out in all matters of social usage and legislation. At present Sweden must be acknowledged to stand on an equality with the foremost nations of the world. In 1912 an accident insurance law was

passed giving a very wide interpretation to the Workmen's Compensation Act. An efficient factory inspection organisation was also set up. Later on (1919) a law was passed limiting the hours of work in industry and allied callings to 48 per week. In 1913 a law was passed instituting compulsory old age and disablement insurance and in 1916 an extended insurance law against accident during work. Legislation on intervention in labour disputes has been revised in 1920 and a law passed setting up a central arbitration court to pronounce judgment in judicial disputes concerning collective labour agreements. The Employers Central Organisation "Svenska Arbetsgivare föreningen" comprised at the end of 1924, 2,112 undertakings employing 231,000 workpeople. About 450,000 of these workers seem to have belonged at the same time to trades unions, and about 300,000 of these to the workers' unions which were branches of the central "lands organisation."

H. von Kochi. (Stockholm 1925). (K. A.)

**SWEDISH LITERATURE** (see 26.214).—The years 1910-25 are not marked by the appearance of any writer of such individual prominence as Fröding, Strindberg or Almqvist; nor did any very definite tendency declare itself which can be applied to the period as a whole. But several writers came to the front whose work deserves attention, and whose names, in two or three instances, were also known beyond the borders of Sweden. Apart from much ephemeral pamphleteering, the World War affected the literature of Sweden perhaps less than that of any other European country, its chief result being to turn the attention of thoughtful Swedish writers away from the present and back to the social life of their country during the 19th century. We shall find that many of the best books produced during this period are retrospective in subject. Gustaf Fröding died in 1911 and August Strindberg in 1912. The deaths of A. U. Bååth (1912) and Sophie Elkan (1921) have also to be recorded.

Not much need be added regarding the later production of authors already well established before 1911. They were either silent or worked on lines already familiar. Per Hallström began what will probably become the standard Swedish translation of Shakespeare. Selma Lagerlöf supplemented her romances with a volume of reminiscences centred round the old home of her family, *Mårbacka* (Eng. trans., 1924), in which the reader will find again much of the atmosphere of *Gösta Berlings Saga* (1891). Though the work itself does not fall within this period, perhaps the outstanding literary event was the publication (1908-11) of the *Memoirs, 1782-1861* in four vol. of Malla Montgomery-Silfvelstolpe. The circumstances of her life brought Malla Montgomery into contact with the most significant figures in the social and intellectual Sweden of her time, in particular with the eminent writer Erik Gustaf Geijer and his Upsala circle, and she was personally well qualified to be the intimate chronicler of the age. The charm and freshness of her writing make the book one of the most delightful in memoir literature, and as a document it is indispensable.

Among the more notable novelists we find on the whole more originality among the women than among the men, some of whom still reflect the influence of Strindberg in certain aspects of their work. Hildur Dixelius-Brettner in her trilogy of three generations, *Prästdottern* (1920), *Prästdotterns Son*, *Sonsonen* (1922) achieved an admirable unity of feeling, essentially tragic, but tempered by the humour of real life. Elin Wägnér came to the fore with *Pennskafjet*, a bright and witty novel of feminist Stockholm; she later established a more permanent reputation with *Åsa-Hanna* (1918) and *Den namnlösa* (1922) which show a deep human sympathy and some tragic power.

The novels of Sigfrid Siwertz are studies in degeneration, marked by sure psychological insight. The most remarkable of them, *Selams* (1920), Eng. trans. *Downstream* (1922), is a family history of the now classical Rougon-Macquart type, but

concentrated in a single generation; the workmanship is of high order, but the picture suffers somewhat from lack of relief. His later novel, *Hem från Babylon*, by drawing on the bizarre and fantastic, gives the impression of a paucity of human material. Among retrospective novels of Swedish life Erik Fahlman's *Firman Åbergson* (1914) stands out as the work of a true artist. The hero is a self-made provincial of the mid-19th century with all the virtues and limitations of his race and time. The texture of the book is extraordinarily light, and the subtlety with which the author has created his atmosphere is altogether admirable. K. G. Ossiannilsson, who began (in a way that is almost a tradition with Swedish writers) as a lyricist, later published a number of novels of contemporary life. He is a writer of originality who has the courage of his opinions and has not shrunk from exposing himself to attack and political isolation by his frankness. His *Bondlandet* (1919), a novel of country life, is a good character study, clearly treated. In *Förtrollningen* (1924) he deals with modern hysteria with some force.

Less clear in his method, but full of vivacity, is Ludvig Nordström, most of whose work bears the general title *Skildringar ur Svenska Nationens Lif*. He is most successful in *Landsorts-bohème* (1912), a thoroughly amusing satire on provincial bohemians, with the editor of the local paper for its central figure. A later work, *Döda världar i Samhällsrymden* (1920), is an ambitious attempt to deal in a fantastically satirical vein with the industrial evolution of Sweden and the effect of new economic conditions on the life of the country. Nordström is tempted by great problems, but seems to lack the balance for carrying them out; his doctrine of "totalism," as he calls the solidarity of the intellectual and the economic life of the nation, appears to have fallen on stony soil, and he is at his best when restricting himself to a smaller scene.

It may be said generally that Swedish humour has a tendency to run to irresponsible lengths and to substitute burlesque for satire. Though not entirely free from this propensity, Hjalmar Bergman in his best work, *Markurells i Wadköping* (1919), Eng. trans. *God's Orchid* (1924), succeeded in blending together tragedy, high comedy and farce while never outraging our sense of fitness and psychological probability. This book, the action of which is concentrated into a single day in the life of a provincial town, is something of a *tour de force*, but at the same time a remarkably trenchant study of character. Henning Berger (1872-1925) was a realist of pessimistic outlook, whose strength lay in the delineation of the life of great cities. His best work is the *Dreamland* trilogy, in which he depicts with great variety of treatment the loss of illusions suffered by Swedes of the educated class in America and the brutalising effect of standardisation on the mental and moral character of the individual. Returning to Stockholm in *Fata Morgana* (1911), his banker hero has renounced his ideals and settled down to a comfortable epicurean view of life. Berger's later work, in the more confined atmosphere of the Scandinavian capitals, lapsed into the novel of scandal, which considerably limits its interest. A lyricist of serious outlook and melodious quality arose in Anders Österling.

To sum up: While contemporary literature affords an admirable retrospect of 19th century life and manners, the future historian will only find in it fragmentary and distorted material for a picture of the 20th. Writers in their dread of the commonplace have exaggerated the exceptional and fantastic, thereby detracting from the documentary value of their work. But this is a fault which is not peculiar to the literature of Sweden.

**BIBLIOGRAPHY.**—Fredrik Böök, *Sveriges moderna litteratur* (1921); Gunnar Jörn, *Svenska diktarporträtt* (Uppsala, 1924). (A. G. C.)

**SWIMMING** (see 26.231), a sport in which many changes have been witnessed since 1910. In 1910 F. E. Beaurepaire of Australia scored a series of remarkable victories in English championships, winning every event from 100 yd. to one mile inclusive. The following year an Hawaiian, Pau Kahanamoku, H. Hebner of Chicago and George Hodgson of Canada, set up world's records at the Stockholm Olympiad.

Apart from the prowess of the foregoing, the Stockholm fixture was noteworthy for the advent of women into Olympic swimming

contests. Miss Fannie Durack of Australia won the sprint in record time, while a quartette of British ladies secured the team event. A year later J. G. Hatfield of England came to the front, and proved supreme in all distance events. Naturally, international swimming fixtures were completely suspended during the War period, yet marked progress was recorded in the United States and to a lesser degree in European countries.

**Improvements in Method.**—The American coaches, L. de B. Handley, New York, F. J. Sullivan, Princeton and Chicago, and W. Bachrach, Chicago, evolved a new variety of the crawl stroke which proved so effective over distances up to one mile that the trudgeon stroke has been rendered obsolete. Handley's experimental work was restricted to the members of the Women's Swimming Assn., New York, and within five successive years he was solely responsible for the development of five world champions, Claire Calligan, Ethelda Bleibtrey, Charlotte Boyle, Helen Wainwright and Gertrude Ederle. In the Middle West, Sullivan and Bachrach brought to light notabilities of the calibre of Perry McGillivray, Harry Hebner and Norman Ross.

Sweden also discovered Arne Borg and Ovar Trolle prior to the cessation of hostilities, whilst the appearance of the American-Belgian, Martial Van Schelle, in International contests against France, Sweden and Holland in 1919, proved a factor of progressive import.

**Olympic Games.**—The governing swimming associations in Great Britain ceased operations during the War; but in certain areas commendable efforts were made to keep the flag flying by intensive work among juniors, and the reward exceeded all expectations. Britain's only Olympic success at the Paris Games was scored by Miss Lucy Morton, who first came into prominence in 1915. Apart from Miss Morton the junior coaching propaganda was directly responsible for the rise to fame of Miss C. M. Jeans, Miss H. M. James, Miss I. Gilbert, Miss G. Carson, Miss M. Spencer, Miss D. B. Hart, A. Rawlinson, R. Flint and W. Stoney, all of whom won national titles in the post-War period.

The Olympic Games at Antwerp in 1920 supplied convincing proof of American supremacy, for the Stars and Stripes were carried to success in the free back stroke and team events in record time, but the breast swimming fell to Scandinavian contestants. New records were established with clockwork regularity. The Hawaiian-Americans, Kahanomoku, in the 100 metres (1 min. 12-5 sec.), Kealoha, in the back stroke 100 metres (1 min. 15-5 sec.), being the outstanding performers among the men, whilst Miss Bleibtrey set up new world's figures for 100 metres (1 min. 13-5 sec.), and 300 metres (4 min. 34 sec.).

The Antwerp Olympiad was noteworthy for the advent of mere school children into the Olympic Games. Nils Sköglund, a 14 year old Swedish boy, took second honours in the men's high diving event, and Miss Aileen Riggan, a 13 year old American, earned world fame by annexing the fancy diving contest against all comers, with her 14 year old countrywoman, Miss Helen Wainwright taking second place. Swedish nominees took the high diving for men and women, but the fancy diving fell an easy prey to America's representatives.

The Americans' speed, style and form, made a tremendous impression and their strokes were immediately copied throughout the world. Arne Borg, in Sweden, Andrew Charlton, in Australia and Miss Hilda James, in England, made noticeable improvement, whilst New Zealand developed a quartette of women who held forth the promise of rivalling the Americans. In 1922 Miss James visited America, but although she showed world record pace she was defeated by Miss Ederle and Miss Wainwright, the English girl's only important success being her victory in the National Medley Championship at Indianapolis. Arne Borg made a world tour in 1923 when he met the 16 year old Australian, Andrew Charlton, the latter proving successful in three contests, when new records were tabulated. Borg, however, eclipsed Charlton's figures later, when he had become acclimatised.

Under the mentorship of W. Bachrach of Chicago, the Illinois Athletic Club produced John Weissmuller, a well-set-up youth of Austrian descent. Weissmuller created world's figures for

every distance from 50 yd. up to and including 500 metres; he also proved equally skilful when swimming on the back, establishing world's record for 100 metres and 150 yards. Weissmuller won the 100 and 400 metres events at the Olympic Games at Paris in 1924, his respective times being 59 sec. and 5 min. 4 1-5 seconds. In the 400 metres Weissmuller was forced to his utmost to defeat Arne Borg and Charlton, as only 2 2-5 sec. separated the first three. Charlton, however, won the 1,500 metres in 20 min. 6 2-5 sec., breaking the Olympic and world's record of 22 min. flat created by the Canadian George Hodgson at Stockholm in 1920.

America almost swept the board at Paris, but it was noticeable that other countries including Sweden, Australia, England and Japan were rapidly closing up to the Americans. Takaishi, a tiny Japanese, returned 1 min. 1 2-5 sec. in the 100 metres, and in the 1,500 metres semi-final he returned 21 min. 58 3-5 sec. Japan took fourth place behind America, Australia and Sweden in the 800 metres Team race, finishing 14 1-5 sec. ahead of the British team. In August 1926 Gertrude Ederle of New York created a record by swimming the English Channel.

**SWINTON, SIR ERNEST DUNLOP** (1868– ), British soldier, was born Oct. 21 1868 and commissioned in the Royal Engineers in 1888. In the South African War he was first adjutant and then commander of the 1st Railway Pioneer Regiment. In 1904 Swinton produced *The Defence of Duffer's Drift*, a tactical study which became an unofficial textbook in the British and Indian Army, and an official one in the U.S. Army. In 1909, when an instructor at Woolwich, he wrote, under the pseudonym of Ole-Luk-Oie, a book of short stories entitled *The Green Curve*, which, by its combination of literary power and military imagination, gained a wide reputation. Appointed secretary of the historical section, Committee of Imperial Defence, in 1910, he compiled the official history of the Russo-Japanese War. This work, which led him to grasp the dominating rôle of the machine gun in future warfare, was to prove, in conjunction with his active interest in the early caterpillar tractors, a vital factor in the causation of the tank. Soon after the outbreak of war in 1914 he was sent out to France by Lord Kitchener as the official Military Correspondent ("Eyewitness"). In this capacity he was able to appreciate the complete paralysis of the offensive brought about by the defensive power of serried machine guns and aggravated by wire entanglements. Swinton was the first to diagnose and suggest the antidote to this tactical disease, and his proposals to Sir Maurice Hankey, Secretary of the Committee of Imperial Defence, in Oct. 1914 became the first link in the causation of the machine gun and wire destroyer, afterwards christened the tank (*q.v.*). In 1915 he returned to England to become secretary to the War Committee of the Cabinet. In this capacity he had much to do with the preparation of the first tanks. He was created K.B.E. in 1923 and in 1925 was appointed Chichele professor of military history at Oxford.

**SWITZERLAND** (*see* 26.238), a republic of Central Europe, bounded N. by Germany, E. by Austria and Liechtenstein, S. by Italy and W. by France. Its area is 15,975 sq. m. and the population (1920) 3,880,320.

### I. POLITICAL HISTORY

**Constitutional Changes.**—The uncompromising nature of the Treaty of Confederation, 1815, actually caused the civil war of 1847, but the Constitution of 1848, amplified in 1874, has never been entirely reorganised. In 1891, however, the right of demanding *partial* reorganisation was conceded to any body of 50,000 Swiss citizens. This democratic measure, proposed some years earlier, had met with little opposition, and it soon proved of great value.

Proportional representation, on the contrary, though put

forward at the same time, had a long and bitter struggle before it. Owing to the peculiar opportunities afforded them by the Federal System the cantons, individually, were able to demonstrate the advantages of the new method of representation by adopting it for the Cantonal Council elections. Between 1891 and 1905, therefore, proportional representation was adopted in several cantons, but the promoters of the whole movement were almost exclusively the Minority parties—Socialists, Conservatives and Liberal Democrats—whereas many of the Independent Radicals (in power since 1848) seemed more and more in favour of increased centralisation and extension of the powers of the Federal Assembly. These were inclined to oppose the adoption of the new method for the election of the National Council, and the struggle continued with more or less heat, until the reaction against the over-centralisation due to the temporary exigencies of war-time gave added strength to the movement, and proportional representation was adopted in 1919.

During this time direct popular election of the local executive authorities had been introduced in a good many cantons, but suggestions that the same method should be applied in the case of the Federal Executive met with no encouragement. As Switzerland has no so-called "Parliamentary System," her central government is very firmly established, and she is therefore able to carry out great public enterprises with the utmost thoroughness and consistency.

**Social Legislation.**—A striking example of this was the building up of the system of social legislation. A proposal for insurance against sickness and accident was rejected by referendum in 1900, but a clause in the same bill dealing with military insurance came into force in 1901. In 1911 the rejected clauses were submitted to the people on a new basis and this time accepted. The opening of the Swiss Accident Insurance Institute in Lucerne in 1918 was, however, merely a compromise; compulsory insurance against old age and sickness, and insurance in favour of surviving dependents were not secured until 1925, when, in order to forestall an extreme measure on the part of the Socialists, the other parties voted for the insertion of a suitable paragraph in the Constitution.

Another example of social legislation was the introduction of the eight-hour day or forty-eight-hour week (in certain exceptional cases fifty-two hours being allowed), by means of the Hours of Work Act of 1921, an extension of the Factory Act of 1914. Although this measure struck a decided blow at economic Liberalism, it was not a sign of State socialism; the Swiss nation has never favoured a tendency in that direction. Thus a motion for the introduction of a direct Federal Tax was defeated by a large majority in 1917, as was also a Property Tax proposed by the Left in 1922. The feeling against extreme centralisation was so strong that the Confederation never even succeeded in getting complete control over military affairs, and to this day the cantons still retain certain powers.

It was, however, otherwise with regard to the consolidation of the legal system, though that also, had been opposed in the past. After long and careful preparation, the Swiss Civil Code came into force on Jan. 1 1912, and, though the task of establishing a uniform Penal Code has not yet been brought to a successful close, a firm foundation has been laid for this also. The draft has been actively opposed in certain cases—for instance, the existing Penal Code of the Catholic Canton of Fribourg was revised a short time ago—so that there seems little likelihood of it being accepted in the near future.

**Extension of Federal Powers.**—Owing to this extension of their powers and the continual development of the administration, the strength of the Central authorities steadily increased. The Confederation was endowed with more and more power in matters calling for uniform treatment, such as the control of waters and forest throughout the country. By the year 1906 the scheme for the State purchase of the railways had already been suggested, and, when the Canton of Ticino proposed selling part of its water-power to a foreign country, the Federal Assembly decided to make the export of electric power, if obtained from the national waters, subject to the approval of the

Federal Council. The National Waters Act came into force on Dec. 22 1916, but its importance was not generally recognised until the Federal Railways were electrified.

*Railway Purchase.*—The State purchase of the railways, however, and the establishment of a bank of issue—the National Bank of Switzerland—tended more than anything else to strengthen the authority of the Confederation. The dislike of the people to any very great concentration of economic power in private enterprise had manifested itself more particularly in connection with these questions; but, on weighty economic grounds, the development of the railways during the latter half of the 19th century was only feasible by means of private capital. In the first decade of the new century conditions were very different, the various railway lines had already justified their existence and there was much less reason to fear rash and expensive undertakings. Notwithstanding all this, there was a good deal of opposition to the proposal of State purchase, but it was due less to economic considerations than to apprehensions of the ever-growing power of the Central authorities, which was felt in some quarters to be not altogether in accordance with Liberalism and Federalism. Indeed, in face of the deficit accumulated during the War years, the question of handing the railways back to private enterprise was mooted from time to time in the country.

Public opinion was excited most of all, however, by the St. Gothard Convention, concluded with Italy and Germany in April 1923, after three years of controversy. An agreement of some sort was inevitable, as these countries had subsidised the construction of the Swiss railways, but the terms of this Convention, which gave them most favoured nation treatment on all the railways throughout Switzerland, and restricted Federal rights in the matter of fares, was regarded by many as a serious limitation of the sovereignty of the State and of economic freedom. So strong was this feeling that the people demanded that, in future, no convention should be concluded by the State for a period exceeding 15 years, without being first subjected to a referendum. This proposal was adopted by plebiscite and consequently became law.

*Neutrality.*—When the World War broke out in Aug. 1914, Switzerland was confronted with new and difficult problems. The army was at once mobilised as a protective measure and on Aug. 4 the Federal Council issued a formal Declaration of Neutrality to those States which had guaranteed her inviolability and neutrality in 1815, and to some others, among them Italy. This declaration expressly stated that Switzerland would maintain the neutrality and inviolability of her territory with all the means at her disposal. The Federal Council, endowed with plenipotentiary powers in this respect also, took the necessary measures for securing the national credit and solving the serious economic problem. Agreements were made with the belligerents on either side with the object of ensuring a constant supply of foodstuffs, and, as a result, the "Société Suisse de Surveillance Économique" (S.S.S.) was established on the one hand, and a "Central Office" (Treuhändstelle) for trade with Germany and Austria on the other.

The newly founded "Agence des Prisonniers de Guerre" opened a fresh field of activity to the committee of the International Red Cross and rendered very great service to all the belligerent countries. Switzerland also acted as intermediary for the exchange of seriously wounded prisoners, and for the repatriation of interned civilians, while many of the sick and wounded, both prisoners of war and civilians, regained health and strength when transferred to the internment camps in Switzerland. (See RED CROSS.) During the War, too, the Swiss Legations in many countries took over the representation of the interests of foreign powers, and this work assumed such proportions that a special department was created to deal with it. The diplomatic representation of Liechtenstein was handed over to Switzerland permanently, a Customs Union was arranged between the two States in 1923, and the Confederation afterwards took over the postal, telegraph and telephone services of the Principality.

*Relations with Russia.*—A Soviet delegation visited Switzerland in 1918, but it acted mainly as an organ of propaganda and espionage, and the revolutionary tendencies of the general strike in that year were undoubtedly aggravated by its influence. The difficulties of the military in counteracting these tendencies, together with the suffering caused by a widespread epidemic of influenza, roused public feeling, and the delegation was requested to leave the country. The assassination of Vorovsky, the Soviet Minister to Rome, on Swiss territory in 1923 widened the breach and no diplomatic relations had been established between the two Governments up to 1926.

*The Savoy Free Zones.*—Under Art. 435, the Treaty of Versailles guarantees the perpetual neutrality of Switzerland but deprives her of the right of occupying Savoy, a right she had been unable to exercise since it was conferred in 1815, as the conditions of occupation had never been defined. Considering the political situation in Europe, the possible exercise of this right, or even its continued existence, would have been a menace rather than a safeguard and might have involved Switzerland in international complications inconsistent with her neutrality. Under the same Article, the Treaty provides for a re-adjustment of the (Free Trade) Zones question by an agreement between France and Switzerland. France has since declared herself ready to accept the decision of an international Court of Arbitration, but the question still (1925) remained unsettled, nor has the neutrality clause yet been ratified.

*Entry into the League.*—The principle of neutrality played a great part in determining the entry of Switzerland into the League of Nations, and its influence was two-fold. On the one hand, it seemed to bind the country to steer clear of all international conflicts and thereby to debar her from joining the League, while, on the other, the interests of the Confederation, as a neutral State, were centred in the very objects which the League was called into being to attain. The Federal Council took keen interest in the new organisation from the outset, and tried by every possible means to ensure the entry of Switzerland. Moreover, Geneva had been selected for the headquarters of the League, and it would have appeared somewhat ungracious had Switzerland refused to join, and thus increased the difficulty of establishing the League. As the question was, of course, subjected to a referendum, the decision of the people in this instance became a matter of international importance.

The taking of the referendum was delayed, for, in a reply to an "aide-mémoire" sent by the Federal Council in Dec. 1919, the Great Powers stated that "a declaration of entry which was subject to the result of a referendum could not be regarded as an entry at all." Still greater uneasiness was caused, however, by another passage in the reply. This stated that the Conference of Ambassadors in Paris, under the presidency of M. Millerand, were deliberating as to whether the entry of Switzerland into the League would be consistent with the maintenance of her neutrality. After drawing up a Memorandum and sending a special mission to London, the Federal Council received a Note stating that the Allied and Associated Powers were bound by Article 435 with regard to the perpetual neutrality of Switzerland, and that all other questions had been referred to the Council of the League. A delegation from the Swiss Confederation obtained an audience of the Conference in Feb. 1920 and in the same month all difficulties were overcome by the decision that Switzerland should be required to co-operate in the case of economic sanctions only.

The fact that the independent existence of little nations side by side with great and powerful states is recognised, not as a mere matter of expediency but as their just due, is in itself a splendid tribute to the liberal and humanitarian tendencies of modern political thought. It behooves these little nations to participate in any international movement serving the interests of humanity, and the large majority, when the referendum was taken in May 1920, showed that Switzerland was ready and willing to take her proper place and enter upon the new phase of her history which began with her enrolment as a member of the League of Nations.

The Swiss delegation to the League maintained an attitude of extreme reserve with regard to all questions connected with the application of the Peace Treaties, with the exception of three which had a special interest for Switzerland. These were the Armenian question, on humanitarian grounds; the question of Minorities, which Switzerland was peculiarly fitted to deal with; and the reconstruction of Austria and Hungary, which naturally aroused her warm sympathy. The League appointed a Swiss to preside over the League Council at Danzig, and two Swiss acted for the League in the Saar basin. From the outset, however, Switzerland regarded the maintenance of peace as the primary object of the League and she therefore was a keen advocate of the Permanent Court of International Justice as the best means of attaining it. M. Max Huber, whose appointment had been moved by Switzerland and Austria, was made Judge of the Permanent Court in Sept. 1921, and in Sept. 1924 he was elected President.

## II. DEFENCE

The Swiss Army is a national militia. Its only permanent forces with the colours are the corps of instructors and the fortress guards. The Federal Council is the supreme head of the military administration and the Federal Govt. is in charge of all larger military questions, although the cantonal authorities exercise part of the administration and promote officers up to the rank of captain. Service is compulsory and universal. Liability to serve extends from the 20th to the 48th year, the first 12 years being passed in the "Auszug" or "Elite," the second eight in the Landwehr, and the last eight in the Landsturm (cavalry, 11 years in the Auszug, eight in the Landwehr). The recruits' courses last 90 days for cavalry; 75 for artillery, air force and fortress troops; 65 for infantry and engineers and 60 days for other arms. Troops in the Auszug then do annual "repetition courses" lasting 11 days (14 days for artillery and fortress troops). In the Landwehr there is only one course every four years.

Switzerland is divided into six divisional districts. The strength of the first line troops is six divisions and certain army troops. The 1st, 3rd, 5th and 6th Divisions consist of two brigades each of two regiments of three battalions, one brigade of mountain infantry, two cyclist companies, one machine-gun group, 12 batteries of field artillery, two field howitzer batteries, two squadrons of dragoons and one battalion of engineers. The 2nd and 4th Divisions have three infantry brigades and no mountain brigade. A cavalry brigade consists of two regiments. A mountain brigade consists of two regiments of three battalions of mountain infantry, two mountain batteries and one company of engineers. Altogether there are 110 battalions of infantry, 72 field batteries, 12 howitzer batteries, nine mountain batteries and six cavalry regiments (each of three squadrons), besides 12 squadrons of divisional cavalry (guides). There is a staff organisation for three army corps. The peace establishment under training in 1924 was 46,200. The fortress troops, mostly Landwehr, amount to about 21,000 men. The Landwehr is organised in 37 battalions and 36 squadrons. Altogether Switzerland can mobilise nearly 200,000 men (combatants), while the Landsturm amounts to about another 60,000. The air force consists of a flying group, composed of staff, five flights (first line), the pilot's corps, corps of observers, one company photographers and one air park company. The aircraft (including reserve, but excluding training machines) consisted in 1924 of 60 fighting planes, 150 reconnaissance and nine captive balloons. (X)

## III. ECONOMIC AND FINANCIAL HISTORY

The last years before the World War were perhaps the most prosperous in the annals of the Swiss Confederation. Foreign trade had by 1913 reached a *per capita* figure of 850 francs, which is more than 25% higher than the figure for the United Kingdom. The import and export figures clearly reflect the peculiarities of her economic structure. The imports were in

1911 to 1913 divided almost equally between foodstuffs, raw materials and manufactured products. Switzerland, which is after Great Britain the least self-sustaining country of Europe, imported grain from Russia, the United States, Argentina, Rumania and Germany, in the order named; meat, chiefly from France and Italy; sugar from Germany; malt and hops from Austria-Hungary and wine from Spain and Italy. For her raw materials, which made up about one-third of her imports, Switzerland was dependent mainly upon Germany (coal and iron), France (silk and iron), United States and Egypt (cotton about in equal proportions), Great Britain (iron) and Japan (silk).

Swiss exports, although they also had advanced rapidly and had reached their highest figure in 1913, had been relatively losing ground when compared to the imports. Nearly 75% of the export trade was in manufactured goods, raw materials representing little more than 10% and foodstuffs less than 15% of the total exports. The German Empire was before the war Switzerland's most important customer and by far her most important supplier. Great Britain, which before 1914 usually occupied the fifth place among the exporters to Switzerland, coming immediately after her four continental neighbours, was second as a customer and the only important customer whose purchases regularly exceeded her sales.

**Public Finance.**—The public finances were on the whole on a sound basis, and public indebtedness was not high. The revenue of the Federal Government was derived in the disquieting proportion of 85% from the customs, whereas the cantons and the municipalities relied mainly for their revenue on property and income taxes. This general division of indirect and direct taxation between the national Government and the local administrations was well adapted to the needs of peace, but proved untenable in time of war.

## THE WAR PERIOD

Switzerland was peculiarly exposed to the repercussions of the War, not only on account of her geographical position, but also by reason of the composition of her population, the nature of her foreign trade and her system of public finance. The main demographical results of the War are apparent if we compare the results of the census of 1910 with those of 1920. The annual rate of increase which had been 12.5 per 1000 inhabitants between 1900 and 1910, fell to 3.3 per 1000 in the succeeding decennial period. The number of foreigners decreased by about 150,000 and dropped from nearly 15% to about 10% of the total population.

The position of Switzerland from 1914 to 1918 may be defined as that of a state politically neutral and economically dependent upon the goodwill of her warring neighbours. The Allies, from whom alone Switzerland could receive the raw materials and the foodstuffs without which her population would have been condemned to unemployment and starvation, consented to their entrance only on condition that they should not in any shape be re-exported to the Central Powers. Germany on the other hand, whose coal and iron Switzerland could no more forego than the Allies' grain and cotton, was not prepared to supply these commodities except in exchange for those she needed most, which were foodstuffs. Under pressure of these circumstances Switzerland sought to increase her production of wheat and fuel, while limiting to the utmost her internal consumption.

From 1914 to 1918 Switzerland's imports of raw materials fell from 4,600,000 metric tons to 2,800,000 and of foodstuffs from 1,300,000 to 700,000. The following figures relating to the two fundamental commodities of grain and coal show both the decline in quantity and the increase in value of Swiss imports during the War:

|                                       | 1913 | 1914 | 1915 | 1916 | 1917 | 1918 |
|---------------------------------------|------|------|------|------|------|------|
| Grain (millions of metric quintals)   | 9    | 7    | 7    | 8    | 4    | 3    |
| Value (millions of francs)            | 181  | 163  | 248  | 404  | 257  | 202  |
| Coal (in millions of metric quintals) | 34   | 31   | 33   | 32   | 23   | 21   |
| Value (millions of francs)            | 107  | 100  | 125  | 151  | 159  | 312  |

While Switzerland's imports were then declining very appreciably her exports were on the whole rather increasing. The commodities, the export of which was most stimulated by the War, were embroideries, machinery, chemicals, silk yarn, wrought copper, iron forgings and aluminium.

The revenues of the Federal State, derived mainly from the customs and from the postal, telegraphic and telephone monopolies, declined *pari passu* with the volume of trade. Its expenditure was enormously increased by the cost of the mobilisation and by the measures taken to counteract the rise in prices. The figures relating to the Budget, given below, tell only a minor part of the tale of increasing financial distress because the cost of mobilisation, as also certain exceptional receipts, were not included in the Budget, but were charged to a special capital account.

With the outbreak of hostilities the army was mobilised for the defence of the neutrality and territorial integrity of the country and was partially maintained under arms throughout the War. The total cost of mobilisation, from Aug. 1914 up to the end of 1918, amounted to 1,076,000,000 francs. In order to meet this and other extraordinary expenditure and the rapidly increasing deficits due to secondary causes, new taxes were introduced, existing rates were raised, and loans were floated at home and in the United States. The new taxes were: (1) a general property and earned income tax levied in 1915; (2) a war excess profits tax, introduced in 1916 and (3) a federal stamp tax, which became payable from April 1918 onwards. By the end of 1918 these three sources had yielded about 345,000,000 francs. The surplus of expenditure was covered by 11 public loans, amounting to nearly 1,000,000,000 fr., all of which except 15,000,000 fr. were raised on the domestic market, at rates little exceeding 5%. The main effect of the War on the public finances of Switzerland was that, in spite of very heavy taxation, the debt of the federal State had increased about tenfold from 1913 to 1918, and that the total indebtedness of the cantons had nearly doubled.

The surplus of births over deaths, although somewhat less than it had been before 1914, is still (1926) between 6 and 7 per 1,000 inhabitants. As the population did not increase after the War in proportion, there must have been an excess of emigration over immigration.

An unemployment crisis which followed was for a time relatively more severe than the British, and similarly entailed state assistance to the unemployed. Fortunately for Switzerland it proved less persistent. By the end of 1923 the worst seemed to be over, and statistics for 1924 and 1925 showed a marked increase in almost all branches of manufactures and a corresponding decrease of unemployment.

But the great menace to the economic prosperity of Switzerland, which is so clearly dependent upon its export trade, is the recrudescence of protectionism all over the world, not least in Switzerland herself. No country can suffer more than Switzerland from the spread of economic nationalism and none should more warmly welcome a wholesome return to a spirit of real international co-operation in the economic field.

When the War was over, the general expectation in Switzerland was that public revenue would automatically increase with the return of economic prosperity and that public expenditure would no less automatically shrink with the decline in the cost of living and the diminution of state activities. In order to redeem the public debt the people, by means of a constitutional referendum, had, on May 4 1919, authorised the introduction of a renewed direct federal War tax on property and earned income. This tax was to be levied yearly until its yield, added to that of the already existing excess war profits tax, would have sufficed to pay off the mobilisation expenses. These expectations were not fulfilled. The ordinary annual revenue increased, it is true, from 101 million francs in 1918 to 283 million in 1924. But the ordinary expenditure increased at a faster rate than the ordinary revenue and the mobilisation cost, which disappeared from the so-called annual capital account, was almost equalled in amount by the extraordinary expenditure.

The public debt actually rose from 1,507,000,000 francs at the

end of 1918 to 2,304,000,000 by the end of 1924. The increased general expenditure was due to the increased debt charges, which to-day far exceed the total pre-War budget, as well as to increased expenditure in all government departments, due to a larger number of state officials with more pay, and in general to higher administrative standards. In the Federal Budget for 1926, the ordinary revenue and expenditure at last almost balanced. A sinking fund was to be set up which should assure complete repayment of the public debt within 40 years.

Foreign Trade (in millions of francs)

|                       | 1913 | 1914 | 1916 | 1920             | 1922            | 1923            | 1924            |

<sup>1</sup> Budget.

**BIBLIOGRAPHY.**—This study is based mainly on public documents which can be readily obtained from the official sources. A complete, thorough and recent work of the economic life and institutions of Switzerland is the following: *Volkswirtschaft, Arbeitsrecht und Sozialversicherung der Schweiz, im Auftrag des schweizerischen Bundesrates Herausgegeben vom Eidgenössischen Volkswirtschafts-departement*, 2 vol. (Einsiedeln 1925). (W. E. R.)

**SYDENHAM, GEORGE SYDENHAM CLARKE, 1ST BARON** (1848— ), British soldier and administrator, was born in Lincolnshire July 4 1848. Educated at Haileybury and Wimbledon, and afterwards at the Royal Military Academy, in 1868 he entered the Royal Engineers. Having served in various expeditions abroad, he returned to England in 1885, and was employed at the War Office until 1892. From 1894 to 1901 he was superintendent of the royal carriage factory at Woolwich. Sir George, who was created K.C.M.G. in 1893, earned a great reputation as an authority on military questions, particularly fortification. On his retirement from Woolwich he was made a member of the committee on War Office reorganisation. In 1901 he was appointed governor of Victoria (Australia), and on his retirement in 1904 he became secretary to the Committee of Imperial Defence. From 1907 to 1913 he was governor of Bombay. He had been created G.C.M.G. in 1905, and in 1913 was raised to the peerage. In addition to his classic work on *Fortification* (1890; 2nd ed. 1907), his publications include *The Navy and the Nation* (1897) and *Imperial Defence* (1898).

**SYDNEY, Australia** (see 26.278), the capital of New South Wales and the chief port of Australia, had in 1922 a population of 109,970 in the city proper, and 981,400 in the metropolitan area in 1923 (over a million in 1925). The city has an area of 3,327 ac., and the metropolitan area, which includes 40 neighbouring municipalities, Kuringgai, and the islands in Port Jackson, covers 185 square miles. The population increased by 42% between 1911-21, and the proportion borne by that of the metropolitan area to that of the whole State had risen to 44% in 1923. The death-rate is low, 8.9 per 1,000 in 1922 and 9.6 per

1,000 in 1923, and in 1922 the infant mortality rate fell to 56 per 1,000.

Since the World War many buildings have been divided into tenements and flats, owing to the scarcity of houses. To guard against the growth of slum conditions much has been done recently in town planning and the destruction of insanitary areas, and several model suburbs have been built. A large number (11,321) of new buildings were authorised in 1923-4. There are 647 ac. of parks and open spaces in the city and 3,700 ac. in suburban areas. Zoological gardens were opened in Taronga Park, to the north of the harbour, in 1916. Work on the city and suburban electric railway, begun in 1916, was stopped in the following year, and was not resumed until 1922. There were 292 m. of tramway track in 1923. Two large storage dams were in course of construction in 1925 and another was sanctioned. In 1923 Sydney possessed 4,173 industrial establishments, 62% of the total for New South Wales, manufacturing mostly clothes and machinery. About half the wool export of Australia is dealt with in the wool sales. In 1913 a Commonwealth bank was inaugurated and a mint for bronze and silver coinage in 1916. A State conservatorium of music was opened in 1915.

Since the foundation in 1901 of the Port Trust, which now controls 57.950 ft. of wharfage, a large reconstruction scheme has been carried out in the harbour. It includes the demolition of old buildings on the water front in order to widen streets and erect houses for harbour workers, and a new road 100 ft. wide along part of the front; also wharves, jetties and sheds and much work on dredging. There are now 136 berths (91 of them in Darling Harbour), equipment for wheat shipment on a spit called Glebe Island, an explosive store on Spectacle Island, fire-fighting apparatus on Goat Island, a coal and oil depôt at Ball's Head, and a naval depôt on Garden Island (Sydney being a first class naval station). Fort Denison is now a lighthouse. Of the 14,284 ac. of water in the harbour about 3,000 have a depth of 35 ft. and over. A contract was signed in 1924 for the construction of a bridge with an overall length of 3,370 ft. across the harbour from Dawes Point to Milson's Point, for rail and vehicular traffic. The foundation stone was laid in 1925 and the work was estimated to take six years. Sydney claims the largest tonnage in the British Empire after London, Liverpool and Cardiff. Trade had almost reached the pre-War level in 1923.

**SYKES, SIR MARK** (1870-1919), British traveller and politician, was born March 16 1879, the only child of Sir Tatton Sykes, 5th Bart., of Sledmere, Yorks. He was educated at Beaumont College, Windsor, and afterwards at the Ecole des Jesuites, Monaco, and Jesus College, Cambridge. He served in the South African War (1902), in 1904 became secretary to Mr. George Wyndham in Ireland and in 1905 went to Constantinople as honorary attaché to the British embassy, remaining there until 1907. Before this, however, he had begun a series of travels and explorations, especially in Turkey and the Near East, and published *Through Five Turkish Provinces* (1900); *Dar-ul-Islam* (1904); and *Five Mansions of the House of Othman* (1909). He also prepared maps of the northwestern region of Mesopotamia and of the southern districts of Palestine, and his knowledge of these regions proved invaluable during the World War. In 1911 he was elected to Parliament for Central Hull as a Conservative, and in 1913 he succeeded his father as 6th baronet. On the outbreak of War in 1914, Sir Mark Sykes raised a battalion of the Yorkshire Regiment, but did not proceed with it to France. He was sent on important special missions to Russia, Mesopotamia and Syria, and published in 1915 *The Caliphs' Last Heritage*. He died suddenly in Paris Feb. 16 1919.

**SYMBOLISM:** see PAINTING.

**SYNGE, JOHN MILLINGTON** (1871-1909), Irish dramatist, was born at Rathfarnham near Dublin April 16 1871. Educated at Trinity College, Dublin, he travelled for some years on the Continent, returning in 1898 to the Aran Isles. Here he wrote a number of sketches dealing with the life of the islanders, which were later collected in *The Aran Islands* (1907). When, in 1904, he became a director of the newly opened Abbey Theatre, Dub-

lin, he had already produced two one-act plays, *The Shadow of the Glen* (1903) and *Riders to the Sea* (1904), published in one volume (1905). *The Well of the Saints*, a three-act play produced in 1905, was regarded by some as an affront to Irish morals, and when *The Playboy of the Western World* appeared in Jan. 1907, it was interrupted every night for a week by an organised disturbance. When the real merits of the play became known, it contributed largely to the fame of the Abbey Theatre. Synge's latest volumes were a collection of his poetical works entitled *Poems and Translations* (1909), and another play, *Deirdre of the Sorrows* (1910) which he all but completed before his death. Synge's greatest work is probably *The Playboy*, though some critics give pride of place to *Deirdre*. Synge died in Dublin March 24 1909.

**BIBLIOGRAPHY.**—W. B. Yeats, *Synge and the Ireland of His Time* (1911); F. L. Bickley, J. M. Synge and the Irish Dramatic Movement (1912); P. P. Howe, J. M. Synge. *A Critical Study* (1912); J. Masefield, *John M. Synge: A Few Personal Recollections, with Biographical Notes* (1915); J. Thorning, J. M. Synge: etc. (1921).

**SYNTHETIC RESINS.**—The nature of synthetic resins may best be realised from a consideration of the character, both chemical and physical, of natural resins (see 23,183).

**Comparison With Natural Resins.**—Synthetic resins possess all or most of the physical characteristics of the natural resins, and in some cases have in addition the distinctive property of hardening under the action of heat. Definite chemical resemblance is perhaps only clearly discernible between synthetic resins of phenolic origin and certain natural resins in respect to the presence of phenolic hydroxyl groups, e.g., acaroid resin and Japan lac are natural resins containing phenolic groups. Synthetic resins are such resins as are artificially produced by the chemical interaction of substances of definite composition. The resins produced in this way are usually of complicated and indeterminate composition. Their importance lies in their industrial use, as substitutes for natural resins in the varnish industry, as insulating material in the electrical industry, and as the basis for the production of moulded articles for ornamental and decorative use, such as umbrella handles, buttons, beads brush backs, doorplates and knobs, etc.

**Formaldehyde-phenolic Resins.**—The growing interest in synthetic resins may be said to date its rise from the activities, about the year 1910, of Dr. L. H. Baekeland in America, and the successful commercial development of a resin from phenol and formaldehyde known as bakelite (*q.v.*). This resin is representative of one main class of synthetic resin prepared to-day, in most countries, in one form or another, by the interaction of phenolic substances, such as phenol and cresol from coal-tar, and aldehydes, such as, particularly, formaldehyde, a derivative of methyl alcohol obtained either synthetically or by wood-distillation. A recent estimate of the world's production of this type of resin divides the monthly output thus: America, 500 tons; Germany, 300 tons; France, 100 tons; Great Britain not less than 10 tons.

**Process of Manufacture.**—The process of manufacture is one of condensation which involves chemical combination with elimination of water. It is usually facilitated by the use of a small addition of acid or alkali. The simplest condensation product of phenol and formaldehyde is saligenin or *o*-hydroxybenzyl alcohol. This is capable of further condensation giving syrupy products which polymerise to a resin somewhat akin to bakelite. No definite conclusions have yet been made as to chemical constitution, owing to the small reactivity of these resins. The fully polymerised formaldehyde-phenolic resin is insoluble in all the usual solvents except nitric acid and caustic alkali. It can only be analysed by combustion which determines merely the proportions of the elementary constituents, carbon, hydrogen and oxygen. Moreover concordant results with these resins are not easy to obtain. Values given by Baekeland for bakelite resin vary as much as from 75.6% to 77.9% for carbon and 5.4% to 6.0% for hydrogen. It is more than probable that the final fully polymerised resin prepared industrially consists, in addition to a polymerised molecule of high molecular weight, of a mixture of small amounts of other substances, which are retained by the

resin during hardening, such as, free phenols and formaldehyde and intermediates formed during the condensation reaction.

**Coumarone Resins.**—The industrial application of resinifying actions of other types has also been developed during the past 10 or 12 years. Coumarone resins, for instance, are prepared from certain fractions distilled from coal-tar naphtha and are used in varnishes. Their method of production involves no preliminary condensation but consists in direct polymerisation of coumarone, indene and cyclic compounds of this class, by means of strong sulphuric acid. Polymerisation is the process by which molecules of relatively simple type become complicated by mutual chemical combination. Resins having physical properties similar to those of the coumarone type can also be obtained by interaction of naphthalene and other aromatic hydrocarbons with formaldehyde in the presence of strong sulphuric acid.

**Miscellaneous Resins.**—Formaldehyde may also be condensed with urea to give transparent colourless resins. These resins have at present limited use in the production of ornamental articles. Colourless transparent resins from thiourea and formaldehyde are being commercially developed in Great Britain. The cheap production of furfural in America from corn cobs is leading to the use of this material as a source of synthetic resin. It condenses with phenol to give a dark and sometimes even black resin.

**General Classification.**—Resins may be grouped according to physical properties, such as solubility. Synthetic resins may be of the class which always remains soluble or of the class which is initially soluble but becomes finally insoluble under the action of heat. Formaldehyde-phenolic resins belong to the latter class of heat-hardening resins. Resins in the soluble class may be further grouped into (a) alcohol or spirit soluble resins, and (b) benzene and oil soluble resins. It is usually found that solubility in alcohol precludes solubility in hydrocarbons like benzene, turpentine and the fatty drying oils.

**Varnish Resins.**—The resins used for varnishes may be spirit soluble (chiefly the formaldehyde-phenolic type), forming substitutes for shellac and the softer varnish resins, such as elemi; or oil soluble (chiefly the coumarone type), forming substitutes for the hard resins like copal. The spirit soluble resins may sometimes be converted into the oil soluble type by a process of melting or "sweating" with a natural resin which acts as a solvent or flux in which further reaction can take place, e.g., Albertol resins are prepared in this way from formaldehyde-phenolic resin and common resin.

**Moulding Compositions.**—The artificial resins used in moulding compositions may be of the heat-hardening or non-heat-hardening type. Moulding resins may be used as pure unmixed resin, when transparent mouldings are usually obtained, or incorporated with some inert "filling" material, such as, sawdust, asbestos or clay, or used for impregnating textile fabrics, particularly paper. In the two latter applications the resin acts as a binding agent for the "filler" or fabric and a particularly durable material can be made in this way when the heat-hardening type of resin is used.

Such material has important use for insulators in the electrical industry, having high dielectric strength, of the order of glass or mica.

**Chemical Classification.**—Two main classes may be distinguished (a) condensation resins, such as those of the formaldehyde-phenolic type, and (b) polymerisation resins, such as those of the coumarone type. The term *polymerisation resin* is used to distinguish a resin which is formed directly by the polymerisation of a chemical compound, without passing through a preliminary stage of condensation. Polymerisation is usually initiated by the action of light, heat, strong acids or alkalis.

**Principles of Resinification.**—Resins appeared to require for their formation the presence of unsaturated atomic groups in the resinifying substance. The well-known drying of linseed oil and other similar unsaturated fatty acid derivatives is a case of resinification due to unsaturation. Chemically speaking, the simplest resinifying group may be considered to be the vinyl group, which forms monosubstituted ethylene compounds—

$\text{CH}=\text{CH}_2$ , and examples of resinifying substances containing this group are styrol or vinylbenzene, isosafrol, isoeugenol, etc.

**Acrolein Resin.**—Acrolein,  $\text{CH}_2=\text{CH}\cdot\text{CHO}$ , is readily resinified and has been proposed in France as a source of synthetic resin for industrial use. Glycerol and phthalic acid react to give a commercially used resin, this reaction being one in which acrolein may be considered to be the intermediate product. Vinyl acetate is being suggested by German workers as a basis for useful resins.

Artificial rubber is a product of the resinification of a vinyl hydrocarbon, isoprene,  $\text{CH}_2=\text{C}(\text{CH}=\text{CH})\text{CH}_3$ . Unsaturation is not alone responsible for resinification; for instance safrol does not resinify in light, whereas isosafrol does, although the constitutions are identical except for the position in the molecule of the unsaturated carbon atoms, isosafrol containing the vinyl group attached to the benzene nucleus. Coumarone resin results from the polymerisation of the pentamethylene derivative, coumarone, which may be looked upon as derived from a compound containing the vinyl grouping. It is possible also to consider fully polymerised formaldehyde-phenolic resins as products derived from the polymerisation of compounds containing vinyl groups, attached to the benzene nucleus, and introduced into the phenolic molecule by means of formaldehyde.

**SYRACUSE, N.Y., U.S.A.** (see 26.302); had a population of 171,717 in 1920, an increase of 25.1% over 1910, of whom 32,383 were foreign born; in 1923 (Staté census) 182,003. The land area in 1923 was 17.78 square miles. Syracuse is situated on the New York State barge canal, opened in 1918, and in 1925 was a terminal for 34 motor-truck lines and six interurban electric lines. Its accessibility and its large hotels and halls (including the coliseum at the State fair grounds, seating 10,000) make it a natural choice for many State conventions. The output of its highly diversified factories was valued at \$49,435,000 in 1909, \$150,691,000 in 1919, \$149,144,581 in 1923. The salt industry, of great importance in earlier years, had disappeared. The consumption of hydroelectric current for industrial purposes (from Niagara and Salmon rivers) was 147,597,039 kw. in 1923. Bank clearings (1924) amounted to \$261,665,876; the assessed valuation of taxable property was \$235,987,840. The public school buildings, including those under construction, had a valuation of \$12,500,000. The acreage in public parks, including the beautiful Onondaga Park, was 2460, and there were 47 ac. in playgrounds. Syracuse University had in 1925-6 a faculty of 500 and an enrolment of 5,250 matriculated students.

**SYRIA** (see 26.305), a State of Western Asia administered by France under a mandate which became effective on Sept. 29 1923. It was definitely detached from Turkey, of which it had previously been a part, by the Treaty of Lausanne, signed July 24 1923. Syria is bounded west by the Mediterranean, south by Palestine and Trans-jordan, east by Iraq and north by Turkey. The total estimated area is about 60,000 sq. m. and population (1925) about 2,500,000; the bulk of which is of Arabic origin.

**Syrian Nationalism.**—One result of the Turkish revolution of 1908 was to give an impetus to the Nationalist movement which had begun some years before to gain ground in the Arabic-speaking provinces of the Turkish Empire, and more especially in Syria. Like other parts of the Empire, Syria was at first disposed to take at their face value the liberal professions of the Committee of Union and Progress. The Nationalists were ready to believe that their aspirations were to be realised, and only awaited a conciliatory gesture. The history of the years 1910-4 is largely the history of their gradual disillusionment, as the atti-

tude of the Young Turks hardened into an intolerant chauvinism. Among the Syrian Nationalists two main tendencies may be distinguished. The more advanced party, which worked through a secret society known as "*Al-Ahd*," preached an Arab war of liberation with a view to the complete independence, not only of Syria, but of the Arabic-speaking provinces as a whole. On the other hand, there was a larger body of opinion which was less interested in Arab independence than in Syrian autonomy, and which put forward a milder programme of practical reforms—administrative decentralisation, the replacement of Turkish by Syrian officials, and the recognition of Arabic as an official language. The Young Turks, however, were in no mood for making concessions.

**Turkish Conciliation.**—It was not until 1912, when Turkey was reeling under the shock of the Balkan wars, that it was thought that something should be done to conciliate the Arabs. Kiamil Pasha, who became Grand Vizier towards the close of the year, allowed a national assembly to be convened at Beirut for the purpose of formulating the Syrian demands. The assembly met in Jan. 1913, but its proceedings were annulled by Mahommed Shevket Pasha, who succeeded Kiamil a few weeks later. The Decentralisation League, which had been founded at Beirut, was suppressed, and the demonstrations of protest which followed were met by the arrest of the ringleaders, which led in turn to a serious outbreak of disorder. In June 1913 a so-called Arab congress was held in Paris. The members were drawn mainly from what may be called the French sphere of influence in the Lebanon and Beirut. The congress adopted a comparatively moderate programme, including the usual demand for decentralisation, and resolved that it should be communicated, not only to the Turkish Govt., but to foreign Powers in friendly relations with Turkey.

The Turkish Govt. was sufficiently impressed to invite three Moslem members of the congress to visit Constantinople. Another conciliatory gesture was the recall of the Vali of Beirut, an uncompromising opponent of concessions to the Arabs, and the appointment of a more liberal-minded successor. A little later a number of Arabs, including some of the militant reformers, were given seats in the Turkish Senate or lucrative appointments in the Civil Service. By these means the Turks succeeded in buying off some of their opponents, but on the main points at issue they continued to temporise, and the Syrian demands received no substantial satisfaction. Thus, those reformers who were in earnest were gradually driven into the arms of the separatists, and on the eve of the war a variety of revolutionary forces were at work in Syria. The malcontents were actively supported by members of the Syrian colony in Egypt, who in turn did their best to establish contact with the representatives of European Powers.

The situation in Syria was watched with special vigilance in Paris. On Dec. 21 1912 the Prime Minister, M. Poincaré, de-

clared in the Senate that "we have traditional interests in the Lebanon and Syria, which we intend to have respected." The Arab congress held in Paris in June 1913 has already been mentioned. Towards the end of 1913 a powerful French squadron visited Beirut. On the eve of the World War France was busily engaged in strengthening her position in the Levant against German competition, and was negotiating for the acknowledgment, on a *do ut des* basis, of her prior claim to railway and other concessions in Syria and Palestine.

**Allied Agreements During the War.**—With the entry of Turkey into the War in Oct. 1914 the future of the Arabic-speaking provinces became a question of immediate concern to the Allied Powers. France promptly asserted her claims in the Levant, and so far as Syria was concerned, as distinct from Palestine, they were never questioned. As between Great Britain, France and Russia the matter was disposed of in the spring of 1916 by a tripartite agreement, which was elaborated as between Great Britain and France by the so-called Sykes-Picot agreement. This agreement, which was concluded on May 16 1916, gave France what was virtually a free hand on the Syrian coast, together with a veiled protectorate over the interior. The situation was, however, complicated by the undertakings already given by Great Britain to the Sherif of Mecca, who was treated as the spokesman of the Arab National Movement. In the autumn of 1915 Great Britain had agreed to "recognise the independence of the Arabs" within certain territorial limits, which did not include the coast of Syria but which clearly included the interior. Not only so, but while the Sykes-Picot agreement laid it down that France should provide any advisers whom the Arabs might require in Inner Syria, the British undertakings to the Sherif could be read as implying that these advisers should be British. There were here the seeds of a misunderstanding which was to have serious consequences.

**War Conditions.**—In Syria itself it looked at first as though the outbreak of war had given the nationalists their opportunity. In the early days of the War the reformers were active in pressing their demands and received some encouragement from a sympathetic Vali. But the tide soon turned against them. Among the French consular archives which were seized in Syria the Turks claimed to have discovered evidence of treasonable dealings with France on the part of a number of the Nationalist leaders. This was the signal for a series of executions and deportations, which began in the summer of 1915 and continued for the next 12 months. For the time being, at least, the Nationalist agitation was completely cowed, and though the Emir Feisal visited Syria just before his father, the Sherif of Mecca, raised the standard of revolt, the Syrian Arabs remained submissive to the end of the War. They had, indeed, little chance of giving trouble. On the one hand, Syria was the base of the Turkish IV. Army, and though it was not always heavily garrisoned, it remained throughout under the shadow of a powerful Turkish force. On the other hand, except for an occasional raid on the coast, Syria did not become a theatre of war until the eve of the Armistice and had no opportunity—even if it had the desire—to co-operate with the Allies. In the autumn of 1918 General Allenby, at the head of the British forces in Palestine, having expelled the Turks from Palestine, swept on after them through Syria. Damascus was occupied on Oct. 1. On Oct. 31 the British cavalry were 15 miles north of Aleppo, and the Armistice which then came into force left the whole of Syria in the hands of the Allies.

**Post-War Settlements, 1918-24.**—On Nov. 7 1918 the British and French Govts. issued a joint declaration, in which they announced their intention of establishing, both in Syria and Mesopotamia, "national governments drawing their authority from the initiative and free choice of the native populations." Meanwhile, it devolved upon Lord Allenby, as commander-in-chief, to make temporary arrangements for the administration of Syria as occupied enemy territory, pending the conclusion of peace. The Syrian sea-board, including Beirut, was placed in charge of the French, while the interior was handed over to an Arab Govt. which was set up at Damascus under the Emir Feisal. The sit-

uation thus created was unsatisfactory to the French, who pressed their claims under the Anglo-French Agreement of 1916. On Sept. 15 1919, the two Powers signed a convention by which the Syrian sea-board came under the direct and exclusive control of France. The interior remained under the administration of the Emir Feisal, but it was now brought within the French sphere of influence, and ceased to be under the general control of the British commander-in-chief. The anti-French agitation conducted by the Arab Nationalists came to a head in March 1920, when an Arab congress met at Damascus and declared "the complete independence of Syria, without any form of foreign interference." At the same time, Feisal was proclaimed King of Syria. Great Britain and France united in refusing to recognise the Syrian kingdom, but the Damascus Nationalists remained defiant and the French found their position untenable. The end came in July 1920, when a French ultimatum to the Arab Govt. was followed by an advance into the interior, the flight of the Emir Feisal, and the entry of French troops into Damascus.

Meanwhile, Syria had been under discussion at the Peace Conference in Paris. On Feb. 6 1919, the Conference heard an Arab delegation, headed by the Emir Feisal, who pleaded the cause of Arab unity and independence. This was followed by complicated, and at times acrimonious, discussions between Great Britain and France. It was eventually agreed in principle that the situation in Syria should be examined on the spot by an international commission of inquiry, but all that actually happened was that two American delegates, Dr. King and Mr. Crane, spent a few weeks in Syria in the summer of 1919. They reported that a French mandate would be wholly unacceptable and recommended that the mandatory Power should be the United States, with Great Britain as a second-best. The King-Crane report, however, had no influence on the course of events, and on April 25 1920 the Supreme Council of the Allies formally agreed at San Remo that the mandate for Syria should be allotted to France. The terms of the mandate were approved by the Council of the League of Nations on July 24 1922, but further delays intervened, and the mandate did not become fully effective until Sept. 29 1923. The situation was finally regularised by the formal detachment of Syria from the Ottoman Empire under the Treaty of Lausanne, which came into force in Aug. 1924.

*French Administration.*—It was, however, the French occupation of the interior in the summer of 1920 which marked the opening of the new régime by bringing the whole country under direct French control. The Lebanon, which the French had occupied at the Armistice, was recognised in Sept. 1920 as a separate "State," with an area considerably larger than that of the pre-War province of the same name. The Lebanon was predominantly Christian, and its administration involved the absorption of a large number of unwilling Moslems. Inner Syria was divided into the "States" of Damascus and Aleppo, together with the "Territory of the Alawiyyin," with its capital at Latakia. Syria was thus broken up into four distinct units, each of them with a separate administration of its own, the only connecting link being the French High Commissioner. In July 1922 the three divisions of Syria proper, as distinct from the Lebanon, were given an opportunity of co-operating in matters of common concern through the medium of a Federal Council. In May 1923 Gen. Gouraud, the first High Commissioner, was replaced by Gen. Weygand, who was responsible for a further rearrangement. By a decree dated Dec. 5 1924 the Federation was dissolved, the States of Damascus and Aleppo were amalgamated into the State of Syria, and the State of the Alawiyyin was reconstituted as a separate unit. In the meantime, some progress had been made, at least on paper, with the development of self-governing institutions. The Lebanon was provided with a representative council in 1922 and the three states of Syria proper in 1923, though in each case the powers of the Council were restricted and were consequently criticised by the nationalists as inadequate.

*The Druse Rebellion.*—Syria contains many turbulent elements, and the French had repeatedly to deal with unrest in various parts of the mandated territory. In 1919–20 they met

with determined resistance in the Djebel Ansariyeh, the northern neighbour of the Lebanon. There was serious rioting at Damascus in 1922 and again in 1925. In the Alexandretta district, in the extreme north of Syria, the French were constantly harassed by Turkish raids across the border, while they also had some trouble with the tribesmen of the desert frontier on the East. In the Druse country in the Hauran there was scarcely a quiet year until 1923, and it was here that the signal was given for the widespread rising which closely followed the arrival of Gen. Sarrail as High Commissioner, in succession to Gen. Weygand, at the beginning of 1925. The Druses rose in open rebellion in July. Their initial successes brought to the surface the latent discontent which existed in other parts of Syria, and it looked for the moment as though the French would be faced with a general rising. A serious situation developed at Damascus, and on Oct. 18–20 the French took the extreme measure of subjecting the city to a 48-hour bombardment. By the end of 1925 the weak French garrison in Syria had been considerably strengthened, and the insurrection had been checked, though by no means completely suppressed. In Dec. 1925 Gen. Sarrail was superseded as High Commissioner by M. Henri de Jouvenel, whose policy was one of conciliation. M. de Jouvenel was not, however, immediately successful. Nationalist opposition defeated his attempt to form a provisional Syrian Govt. under the Sheikh Taher ed-Din, while in some parts of the country, notably at Damascus, the population boycotted the elections which he ordered to be held as a first step towards a *modus vivendi*. By the end of April normal conditions had been partially restored, but Damascus was still in a state of siege. By June 1926, the Druses were mastered, but there is still much underlying unrest.

*Report of the Mandates Commission.*—The circumstances of the rising were closely investigated, on behalf of the League of Nations, by the Permanent Mandates Commission at a special session held in Rome in Feb. and March 1926. The Commission, in its report to the League Council, convicted the French of serious errors of policy and severely censured the conduct of Gen. Sarrail, though at the same time it recognised the difficulties of the mandatory power in dealing with a peculiarly intractable problem, took note of its declared intention to give Syria the fullest possible measure of self-government with a view to its eventual independence, and called upon the Syrian leaders to desist from sterile obstruction. (L. St.)

**SZINYEI-MERSE, PAUL DE** (1845–1920), Hungarian painter, was born at Szinyeujfalu and studied art at the Munich Academy. His first pictures, "The Faun and the Nymph" (1868) and "The Evening Star," were characterised by gay and graceful colouring, a lyric view of nature and a simple mode of placing the elements of the picture. Szinyei soon abandoned the traditional brown undertone and worked with unbroken colours, embraced in a cheerful and suggestive composition. In 1869 he produced his "Mother and Child" and in 1873 finished the masterpiece of his life "May Festival," which was criticised at the time for its alleged "delirium colorans." This so embittered Szinyei that he retired to his country house and for a time produced very little work. "The Woman in Lilac" (1874) and the "Lark" (1882) are products of this period. On returning to work with renewed enthusiasm, he exhibited "Rococo," "Oculi," "Snow-melting" and "Poppies" at Budapest in 1894–5. He afterwards gave successful exhibitions at Munich (1909), Berlin (1910) and Rome (1911). In 1905 he was appointed director of the Hungarian National Academy of Arts. He died in 1920.

**TABLE TENNIS** (see PING-PONG, 21.626).—Table tennis or ping-pong is a game played by striking a small celluloid ball over a net fixed across a table. The ball must be between  $4\frac{1}{2}$  in. and  $4\frac{3}{4}$  in. in circumference and between 2/27 oz. and 2/25 oz. in weight. The net is  $6\frac{1}{2}$  in. high and fixed across the middle of a table 9 ft. long and 5 ft. wide in such a way as to project 6 in. on either side. The upper surface of the table lies 2 ft. 6 in. above the floor, and must be of such resilience that a standard ball when dropped upon it from a height of 12 in. shall rebound to a height of from eight to nine inches. The racket may be of any material or shape. The server projects the ball from behind his end of the table in such a way that it bounces first upon his side, then upon his opponent's side of the table. Thereafter it is struck to and fro to pass directly over the net, very much in the manner of lawn tennis, except that volleying is not allowed. The scoring is by points (a single service counting as a point), 21 in each game; the service changes every five points until the score twenty-all, when the players serve alternately and, as at score deuce in tennis and lawn tennis, the winner is then he who first scores two points more than his opponent.

The game began to revive in England about 1921, at first through the machinery of the old Ping-Pong Association. The following year that organisation was abandoned and a new body was formed under the title Table Tennis Association. The most important centres of the game in England, loosely knit in the fabric of the T.T.A., are the London and Home Counties T.T.A., the Birmingham and District T.T.A., the Northern Counties T.T.A., the Bristol T.T. League and the Sunderland and District Ping-Pong Union. The English T.T.A. is federated to the Table Tennis Associations of Germany, Austria, Hungary, Sweden and Czechoslovakia, in all of which countries its rules are observed with but slight modification. The Table Tennis Association of Wales (founded 1923) has certain rules of its own, among which notably is a prohibition of all but wooden rackets, a rule which is copied locally in Bristol and Sunderland.

The modern attacking game is very fast, probably the fastest in the world except ice-hockey. The attacking stroke is usually made with considerable top-spin, the defensive stroke with under-spin. This predominance of varied kinds of spin in the technique of the game has made the rubber-faced racket the favourite among the younger school of players. Various modifications of the game have been introduced from time to time, but the rules remain to this day substantially the same as those provided for by the old Ping-Pong Association rules of 1913. Notable reforms which have now been rejected by all table tennis players were the attempt, in 1923, to popularise lawn tennis scoring, and the attempt about the same date to introduce a form of play in which volleying was permitted (table lawn tennis). A doubles form of the game in which a white line is drawn down the centre of the table, the server serving the striker-out diagonally opposite to him, and thereafter each partner striking the ball alternately—is sanctioned by most national associations. There is already an etiquette of the game which discourages such practices as wearing white clothes, which may tend to unsight the opponent. It should be noted that the margin in singles at table tennis between a man and a woman of equal class is as great as at lawn tennis—about half the game. The following are the results of the English singles championship since 1922:—

|      | Gentlemen          | Ladies     |
|------|--------------------|------------|
| 1922 | A. Donaldson       | Mrs. Scott |
| 1923 | M. Cohen           | Miss Berry |
| 1924 | Percival Bromfield | Miss Berry |
| 1925 | P. N. Nanda        | Miss Berry |
| 1926 | S. Suppiah         | Miss Vasey |

*Results of Other Matches.*—1923—England beat Wales in London. 1924—England beat Wales at Cardiff. 1925—England beat Wales in London. 1926—Wales beat England at Cardiff. 1926—In Berlin, Hungary beat Germany and English T.T.A. team. Germany beat English T.T.A. team. 1923—Cambridge University Club beat

Oxford University Club at Cambridge. 1924—Cambridge University Club beat Oxford University Club in London. Winners, International Tournament in Berlin—1925, P. N. Nanda (London); 1926—M. Mechlowits (Budapest).

See P. Bromfield, "The Flick Stroke," essay included in *The A.B.C. of Table Tennis*, by J. J. Payne (London, 1924); Ivor Montagu, *Table Tennis To-day* (Cambridge, 1924). (I. Mo.)

**TABRIZ**, Persia (see 26.341), with a population over 200,000, is a commercial centre, and a seat of the carpet-making industry. Trade has been depressed in recent years, though a revival of the export of piece goods through Turkey has brought the route from Hamadan, which connects with the Turkish trade route through Trebizond, into use again to some extent. A railway to Julfa (on the Persian-Russian frontier), where connection is made with the Caucasian lines, was built by a Russian company, opened in 1916 and transferred to Persia in 1921. In 1923 the line was in very bad repair, and trains were only run occasionally when sufficient freight was forthcoming. Tabriz became involved in the World War owing to Turko-Russian conflicts in the vicinity of Lake Urmia, and was occupied first by Turks and then by Russians in 1915.

**TACHOMETER:** see SPEED INDICATOR.

**TACNA-ARICA QUESTION.**—The war between Chile and Peru, begun in 1879, was terminated by a treaty of peace Oct. 20 1883, known as the Treaty of Ancon. Article 3 provided that the Peruvian provinces of Tacna-Arica should be held by Chile for 10 years, after which a plebiscite would determine the sovereignty of those provinces. The country winning the provinces would pay to the other 10,000,000 Chilean silver pesos or Peruvian soles; a special protocol would prescribe the manner in which the plebiscite would be carried out. In 1892 negotiations were entered into between Chile and Peru for carrying out the plebiscite, but these and subsequent ones were unsuccessful. In 1922, however, at the invitation of the United States, issued at the suggestion of Chile and Peru, both governments sent representatives to Washington, and a protocol of arbitration was drawn up on July 20 1922 which set forth that the only outstanding questions between the two countries were those relating to the unfulfilled provisions of Article 3 of the Treaty of Ancon, which should be submitted to the United States for arbitration. A supplementary act provided that in case the arbitrator ordered a plebiscite he was empowered to determine the conditions thereof. The arbitrator's award, dated

March 4 1925, decided that a plebiscite should be held, set forth the conditions thereof and the plan for the payment of the 10,000,000 pesos and decided the definite boundary of the territories involved.

*Plebiscite Ordered.*—In considering whether or not a plebiscite should be held the arbitrator had to determine: first, whether the parties had acted in good faith in not coming to an agreement regarding the special protocol determining the terms of the plebiscite; and, second, whether Chile's administration of the provinces had been such that a free and fair election could be held. The arbitrator decided the first question in the affirmative; and respecting the second, although far from approving the course of Chilean administration or condoning the acts committed against Peruvians, found no reason to conclude from the evidence submitted that a fair plebiscite could not be held under proper conditions.

In order appropriately to supervise and have general control

over the plebiscite, the award set up a plebiscitary commission acting by majority vote, consisting of three members, one each appointed by Chile and Peru and the third, who should be president, appointed by the President of the United States. Registration and election boards were also provided. The arbitrator also reserved the right to entertain an appeal from the acts of the plebiscitary commission, which was to assemble at Arica not later than six months after the rendition of the award, and proceed at once to formulate rules for its own procedure and regulations governing the plebiscite and to fix the time and places for voting. The arbitrator provided that the 10,000,000 should be paid: 1,000,000 within 10 days after the arbitrator's proclamation of the result of the plebiscite, a second 1,000,000 within the following year and 2,000,000 at the end of each of the subsequent four years. The customs revenues of Arica were assigned as security. The arbitrator decided that the Peruvian provinces of Tacna-Arica as on Oct. 20 1883 constituted exclusively the territory in dispute, and that no part of the Peruvian province of Tarata was included therein. Tarata was transferred by Chile to Peru on Sept. 1 1925, the definite boundary being left for determination to a boundary commission.

*Objections of Peru.*—On April 2 Peru objected to the finding of the arbitrator for a plebiscite, maintaining that the meaning of the Spanish text of the Treaty of Ancon was "upon," "at" or "immediately after" the expiration of the 10 years. Peru also requested guarantees for the voting, including immediate evacuation of the territory by the Chilean civil and military authorities and their replacement by Americans. The arbitrator replied on April 9, pointing out the agreed finality of the award and that the translation complained of was the one submitted by Peru. The problem before him was one of substance, of construction rather than of translation, a problem which had been debated by the parties long before the arbitration gave rise to any question of English translation. As to Americans taking over control of the provinces, the arbitrator found that this request went beyond the scope of his authority under the terms of the submission and the findings of the award.

*Meeting of Commission.*—The plebiscitary commission met at Arica on Aug. 4 1925 and drew up its rules of procedure. On Dec. 16 Chile appealed to the arbitrator from a resolution of the commission making the date of the plebiscite; she thought conditional upon Chile complying with certain regulations of the commission. Chile took the position that by these regulations the commission exceeded its power and infringed upon her administrative control of the provinces and that the commission's control over the plebiscite began only with the registration of voters. Chile later withdrew the appeal regarding dates, and the arbitrator, in a decision dated Jan. 15 1926, permitted its withdrawal. He pointed out at the same time that the submission agreed that the arbitrator should determine conditions of the plebiscite; that he had established a plebiscitary commission for this purpose whose requirements had the same binding effect as if prescribed by him; and that conditions for holding a fair plebiscite became the primary concern of the commission from the very moment of its organisation.

The arbitrator held that while the territory remained in Chile's possession and subject to Chilean laws and authority pending the plebiscite, the possession and administrative authority were subject to the provision for holding the plebiscite, the award having stated that the exercise by Chile of legislative, executive and judicial power should not go to the extent of frustrating the provision for a plebiscite. The execution of the requirements of the plebiscitary commission was therefore but the exercise by both parties of their jurisdiction respectively in accordance with their agreement, and was not in derogation of the administrative authority of Chile.

On Feb. 16 1926 the American Govt. proffered its good offices to Chile and Peru in an endeavour to adjust the differences, on the understanding that pending such an adjustment the authority of the plebiscitary commission should be maintained unimpaired. The American offer was accepted by Chile on Feb. 19, with the proviso that the arbitral award must be sub-

mitted for approval to the respective constitutional bodies. Peru was unable to accept the offer, and on March 11 the American Ambassador at Santiago submitted a further memorandum to the Chilean Govt. explaining his Government's interpretation of the term "good offices." Chile reiterated her acceptance of the offer, and Peru having accepted, the Secretary of State, through the American Ambassador, on March 25, suggested that the plebiscitary proceedings should be temporarily suspended, to be resumed later if the differences could only be adjusted by holding the plebiscite.

Chile and Peru appointed plenipotentiaries who met with the Secretary of State on April 6. The Secretary made proposals for the division of the territory between Chile and Peru, for the neutralisation of the provinces, for the transfer of the provinces to a third party and finally a proposal for a corridor to the sea for Bolivia, the territory to the north thereof to go to Peru, to the south thereof to Chile, equitable compensation being made for improvements, et cetera. None of these proposals were accepted by both parties. The last proposal was accepted by Peru, but Chile desired something more definite, namely, the defining of the boundaries of the corridor, and made a proposal setting forth the limits of the corridor. This last proposal was rejected by Peru.

In the meantime conditions in the provinces had not been improved and the plebiscitary commission, being pressed by the Chilean member to fix the date for the elections, voted a resolution on June 14 declaring that Chile having failed in its obligation to create and maintain conditions proper and necessary for the holding of a free and fair plebiscite, the commission found that this failure had frustrated the efforts of the commission to hold the plebiscite as contemplated by the award and had rendered its task impracticable of accomplishment. The commission therefore decided that a free and fair plebiscite as required by the award was impracticable of accomplishment and that the plebiscitary proceedings be terminated. The commission thereupon closed up its work and left the territory after providing that subsequent meetings might be called by the president. (F. WH.)

**TACOMA**, Wash., U.S.A. (see 26.347), had a population of 96,965 in 1920, of whom 21,705 were foreign born, including 1,067 Japanese. The population (1925), was estimated at 104,455. By 1925 the harbour provided berthing space for 60 large vessels; 56 steamship lines made it a port of call; exports and imports had about doubled since 1921, both in tonnage and in value (total handled, 1924, 4,156,590 tons, valued at \$162,317,610); and the publicly owned and operated facilities on the Tide Flats, commonly known as Portacoma Piers, were in process of development. Industrial development also was rapid.

**TACTICS** (see 26.347).—The article TACTICS in the 1911 Edition of the *Encyclopædia Britannica* epitomised the two outstanding features of modern warfare on land as "the development of fire-power" and "the improvement in communications"—brought about by the railway. The experience of the World War fulfilled and amplified this judgment. The following article traces the development of tactical science since 1914. The stages in that development are sufficiently well marked to justify the division of the article into five sections, namely: I. The Effect of Modern Weapons; II. Tactics in 1914; III. The Artillery Bombardment; IV. The Surprise Attack; and V. Post-War Tactics.

#### I. THE EFFECT OF MODERN WEAPONS

The early fighting man had his sword for offensive use, his shield for protection, and used his legs for movement. The soldier of 1914 had weapons—the gun and the machine gun—infinitely more deadly than his prototype, but he had discarded his protection and he still depended on his legs for tactical movements, i.e., on the battlefield. The consequence was to tilt the scales heavily in favour of the defending side, and this adverse balance was increased by the improvement in communications—for the railway enabled the defenders to rush vast numbers of static fire weapons to any threatened point, and so

bar the attackers' path. Fighting or tactical power is fundamentally a compound of power to move, power to hit and power to guard; hence the responsibility for the bloody stalemates of 1914-8 lies with the general staffs of Europe, in their failure to realise that the development of one element without regard to the others made inevitable the breakdown of the war machine. Faced with the deadly reality of modern fire-power, the troops of the warring nations, for want of any form of mobile protection, were forced to fall back on an immobile form—that of entrenchments. And because of the swollen armies which were the outcome of the Teutonic "Nation in Arms" theory, these entrenchments soon stretched from frontier to frontier, rendering offensive action as nugatory as it was costly.

*Stalemate Predicted.*—This blindness of the general staffs is the more remarkable in that a civilian, M. Bloch of Warsaw, had predicted such a result as long ago as 1897. In the preface to his book *The Future of War* he had said: "At first there will be increased slaughter—increased slaughter on such a scale as to render it impossible to get troops to push the battle to a decisive issue. They will try to, thinking that they are fighting under the old conditions, and they will learn such a lesson that they will abandon the attempt forever. Then, instead of a war fought out to the bitter end in a series of decisive battles, we shall have as a substitute a long period of continually increasing strain upon the resources of the combatants. The war will become a kind of stalemate, in which, neither army being able to get at the other, both armies will be maintained in opposition to the other, threatening each other, but never being able to deliver a final and decisive attack. It will be simply the natural evolution of the armed peace, on an aggravated scale. Everybody will be entrenched in the next war. The spade will be as indispensable to the soldier as his rifle. The next war will be a long war, because all wars will of necessity partake of the character of siege operations."

The experience of the war in South Africa led some students but few soldiers to lend an ear to the forecast of M. Bloch. But despite the still stronger confirmation given by the Russo-Japanese War, the general staffs scorned this "amateur" opinion, and continued to predict and prepare for a short and decisive war of rapid movement's.

*Early Lessons of the World War.*—Within a few months of the outbreak of War in 1914 not only had M. Bloch's major predictions—stalemate and siege operations—been fulfilled, but also a host of his detailed forecasts. He had declared that after a battle the victors would not be able to pursue and the retreating force, falling back on new positions a few miles to the rear, would entrench themselves for fresh resistance; that frontal attacks would be impossible without great superiority of numbers; that the loss in officers would be disproportionately great; that cavalry would not even be able to fulfil adequately their rôle of reconnaissance; that the bayonet combat would be almost unknown; that the commanders would not be able to overcome the problem caused by the very magnitude and unwieldiness of the machine which they had created, and that the whole tendency of modern tactics was such as to prevent the nations reverting to armies of a manageable size. "The unwieldiness of the modern army has never been adequately taken into account."

The fundamental defects which have been discussed were, moreover, aggravated by reactionary tendencies which made worse the difficulties already inevitable through the disproportionate improvement of fire-weapons and communications. A study of the French official *règlements* from 1875 to 1914 sheds a significant light on this point. The doctrine of 1875, issued while the battlefield experience of the Franco-German War was still fresh in the memory, approximated more closely than any of its successors to the lessons learnt by the end of the World War. At the end of a war the test imposed by the bullet and the shell has displayed the weak points in the doctrines based on the unreal conditions of peace-time manoeuvres; the methods in use have been hammered out of the molten ore of battle experience. With every fresh *règlement* subsequent to 1875 there was a

swing of the pendulum back towards density of formation, a greater reliance on mere weight of numbers and a disregard of the effects of fire—forgetting that in face of machine-guns density of numbers simply means density of corpses killed by concentrated and relentless fire.

As a result the French infantry went to war in 1914 trained on a doctrine which cost them appalling and futile casualties in the early battles. So also with the Germans. And the root cause of this homicidal reaction was lack of imagination. Not merely the failure to visualise the presence of hostile bullets, but still more the average inspecting officer's dislike of training ground manoeuvres where he could not see the troops, his feeling that an invisible attack was no attack. Thick waves of advancing men and massed assaults have both a pageantry and a force which impress a mind incapable of picturing the stream of bullets from concealed attacking groups as it is of visualising those waves turned into swathes of dead.

## II. TACTICS IN 1914

Let us trace the tactical doctrines on which the chief Powers went to war in 1914. Infantry was regarded as the decisive arm, and the artillery as primarily for its support during the attack rather than to pave the way for and make possible the infantry attack. To quote the French *règlement* of 1913: "Artillery no longer prepares the infantry attack but supports it." The object in the infantry attack was to build up as strong a firing line as possible, by the infusion of reserves close to the enemy's position and then, having gained superiority of fire, to deliver a general assault with the bayonet. The unreal idea of a fire fight on a definite line followed by a synchronised assault made by troops in the open was embodied in the manuals and practised on the training grounds. For the cavalry, shock action by large masses was still believed possible, especially in the French Army, and it is a curious reflection that the one cavalry—the British—who were effectively trained for dismounted action, should have furnished the only, rare, examples of shock action. They at least had recognised that attack mounted could only be by small, dispersed bodies.

*The Firearms of 1914.*—As regards weapons, only the Germans had adequately appreciated the importance of the machine gun, although the British partially offset their lack of these new automatic firearms by the exceptionally high standard of rifle-shooting developed in their professional army. In field artillery France had the advantage with her famous 75-millimetre, unique in its rate of fire, and the German "77" compared unfavourably even with the British 18-pounder. On the other hand Germany alone had really developed the heavy howitzer and the high explosive shell, rather because her general staff planned the rapid reduction of the frontier fortresses than because they foresaw trench-warfare. All armies in fact shut their eyes to the lessons of Manchuria and neglected the study of field entrenchments; expecting and preparing for a war of rapid movement and speedy decision. This decision the Germans hoped to achieve by a grand enveloping manoeuvre, with the mass of their forces on the right wing; moving through Belgium and Northern France with Thionville as the pivot of this vast "wheel."

Partly because the younger Moltke had whittled away the original plan of Schlieffen, partly because the German High Command lost all touch with and control of their wheeling armies, and partly because the rapid advance of such masses proved too great a strain on the supply services, the ponderous machine was thrown out of gear by a relatively light jar on the Marne. The German right fell back to the Aisne line, and there the Franco-British pursuit quickly came to a stop in face of entrenched machine-guns and barbed-wire entanglements—the superiority of the defensive over the offensive became manifest. The so-called "Race to the Sea" ensued, with the rival armies in turn vainly seeking to find and turn the opponent's exposed flank. By Oct. 1914 these flanks reached and rested on the sea, and the repulse of the second great German effort, at Ypres, established the trench-barrier firmly from the sea to the Swiss frontier.

*The Triumph of Defensive Action.*—The tactical significance of the next four years lies in the unceasing attempts, French, British and German, to discover the key to unlock this barrier. While the high commands sought the key in a progressive development of gun-power and its employment in varied forms, certain more original minds endeavoured to find a revolutionary rather than an evolutionary solution. In the words of Field Service Regulations, "Victory can only be won as the result of offensive action"—a phrase which embodies the experience of war throughout the ages. Yet the outstanding fact at the end of the first clash of the World War was the paralysis of the offensive brought about by the defensive power of modern weapons, especially machine guns, and aggravated by wire entanglements. M. Bloch had prophesied this paralysis, the Russo-Japanese War had foreshadowed it, but the military physicians of Europe had refused to listen to warnings from one whom they regarded as a mere "quack" intruding on professional preserves.

But as official historian of the Russo-Japanese war, Col. Swinton, a well-known military writer, had grasped the tendencies of modern warfare, the dominating rôle likely to be played by trenches and the machine gun. By a coincidence he had also taken an active interest in experiments with "caterpillar" tractors. In the early months of the War he was sent out to France as official "Eyewitness" at G.H.Q., and was thus in an exceptional position to diagnose the conditions that had arisen. His previous study gave him the source from which to seek the antidote, and his suggestions to Sir Maurice Hankey, Secretary of the Committee of Imperial Defence, became the first link in the causation of the armoured trench-crossing "machine-gun and wire destroyer," afterwards christened the tank. The receptive mind of Mr. Winston Churchill, then First Lord of the Admiralty, fastened on the idea, already considered in a more limited form, and his driving force carried it through a period of ineffectual experiment and official opposition, until at last it took shape in the original "Mother" tank of 1916 (*see TANKS*).

Meantime, however, on the battlefields of the Continent, there were a long series of attempts to find a more orthodox solution by the "weary process of trial and error." In this article we necessarily exclude those which were made to seek a decision in other theatres of war—expeditions such as that to the Dardanelles which were aimed at the strategic flank of the Central Powers, far distant from the barred front in France—as these fall under the head of strategy, not of tactics. Nor can the limits of space permit us to dwell on innumerable minor innovations in weapons and organisation, most of which tended to still further technical augmentation of fire-power. Among these were the development of the hand and rifle grenade, of many types of trench-mortar, the vast expansion in heavy artillery and the replacement of shrapnel by high-explosive shell, the increase of engineer and signal troops—all of which were the product of conditions which approximated to siege operations rather than to mobile operations in the open field. Even more noteworthy was the vast and rapid progress in the use of aircraft (*see AIR WARFARE*), first for reconnaissance in all its forms, then for artillery observation, later for bombing and fighting, and to some extent for attacking troops on the ground.

### III. ARTILLERY BOMBARDMENT

The first tactical attempt of note to find a solution to the trench deadlock was at Neuve Chapelle, March 10 1915. By hoarding his slender stock of ammunition, the British Commander-in-Chief, Sir John French, was able to open a short but violent bombardment on a sector of the German position. Surprise was achieved for the infantry assault which followed immediately, but the opportunity was lost by the failure to bring up reserves in time and because of the narrowness of the front attacked—the narrower the breach the easier it is to close.

*German Experiments.*—It is a curious reflection that while the British thereafter discarded this promising method in favour of prolonged bombardments which negated the possibility of surprise, the Germans should have profited by it. Meanwhile, however, they essayed a more radical departure from normal methods;

on April 22 at Ypres they discharged waves of chlorine gas from cylinders against a sector of the French front where it linked up with the British. Overwhelmed by a weapon against which they had no protection, the French sought escape by flight, and for a time a complete breach lay open in the Allied line. But the surprise was double-edged, for the German military authorities had not anticipated the success and had no reserves at hand to exploit it. The stout resistance of the Canadians on the flank of the breach, and their prompt reinforcement, warded off the danger—and the Germans lost a golden opportunity.

They were more successful in the development of a borrowed method. Foiled the previous autumn in their plan of crushing France while holding Russia in check, the Germans had resolved to seek a decision on the Eastern Front. Here, with the breakdown of the much heralded Russian steam-roller, a trench stalemate had set in also, though not as firmly knit as that in the west. Falkenhayn, who had succeeded Moltke as chief of the Great General Staff, transferred reserves from France and thus assembled a new XI. Army of 10 divisions on the Dunajec front, between the upper Vistula and the Carpathians at Gorlice. This was placed under Mackensen, with Von Seeckt, the head of the German Army, as his chief of staff. Four hours' intensive bombardment from some 1,500 guns of all calibres ushered in the infantry assault—or rather procession. Stunned and surprised, the Russians could offer little resistance and by nightfall their front was broken through. Prompt exploitation, both in depth and by the other armies on the flanks, led not only to immense captures of prisoners—170,000 in a fortnight—but to a Russian retreat which like a snowball grew and gathered momentum until by the autumn it had rolled back to the line Riga-Pinsk-Dubno. Had Falkenhayn acceded to Ludendorff's pleas and sanctioned his scheme for striking towards Minsk, at the main communications of the enemy, Russia might have been put out of the War that year, and even as it was the loss of nearly a million men in prisoners alone inflicted irreparable damage on Russia's fighting power.

*Champagne and Artois.*—On the Western Front the Entente armies made their next attempt to solve the stalemate, in September. The object was still a rapid break-through, but the method differed, and in fact abandoned the essential element—surprise—for such a purpose. A bombardment of three days' duration—five in Artois—certainly reduced the resisting power of the enemy's advanced troops, but it also gave them ample warning for the concentration of reserves. If the "wheel had come full circle," reviving in a more powerful and prolonged form the "artillery duel" of earlier days, it was a vicious circle. The plan was for the main blow to be delivered in Champagne while a subsidiary attack was launched in Artois, thus menacing the southern and western sides respectively of the German salient Lens-Noyon-Reims. It had two further inherent weaknesses: the first, that the fronts of attack were still too narrow; the second, that they were too widely separated to react on each other.

The double offensive was launched on Sept. 25. In Champagne the Germans' first positions were quickly penetrated, but in proportion as the advance progressed its own force slackened and that of the defence waxed stronger. In Artois, the French attack south of Lens was soon checked, but that of the British at Loos came closer to a break-through. It failed owing to loss of control among the leading troops, the difficulty of communication between the infantry and their supporting artillery once they had penetrated beyond the enemy's first position, and, above all, because the reserves were held too far back. Behind the fronts of attack cavalry masses waited, as at each subsequent offensive, to pass through the breach and carry out the exploitation—which was to prove yet another mirage in the tactical desert of 1914-8. The delaying power of even a solitary machine gun, the extreme vulnerability of the cavalryman, combined to make such exploitation an impossible, though sedulously cherished, ideal.

*Doctrine of the Limited Objective.*—The failure of the Sept. offensives of 1915 widened the cleavage, already apparent, of military opinion into two schools—those who argued that a break-through was still possible if the right lever were found, and those who contended that in default of a genuine new key the

nations must reconcile themselves to a war of attrition. For 1916, however, a common ground was found in the adoption of the doctrine of methodical advances with limited objectives. This was the natural sequel of the new maxim "Artillery conquers defences, infantry occupies them," a tacit recognition that artillery had supplanted infantry as the decisive arm. The depth of ground which could be effectively bombarded fixed the limit of the occupation, and the infantry thus had to halt until the guns could be moved forward. The Germans gave the method its initial trial in the Battle of Verdun, and it had distinct success in the later months, largely because they regained some measure of surprise by increasing the rapidity of fire and decreasing the duration of the bombardment compared with the Entente forces the previous September. An additional reason was their choice of a sector suitable to the method.

For the Entente offensive on the Somme, beginning July 1 1916, the British command also adopted the "limited objective" method, combining it with an artillery preparation even longer than before, and so abandoned any chance of surprise. The Battle of the Somme may also be said to have been the low-water mark of infantry tactics in recent history, the infantry attacking in dense unarticulated lines, or waves, in close succession—which prevented any possibility of manoeuvre, easily lost direction, and were little better than swathes of human grain to be mowed by the enemy's bullets. In many units it was even a mistaken pride to maintain the "dressing" of these lines. There was one new tactical feature, the "creeping barrage," by which the artillery lengthened their range progressively according to a time-table based on the calculated rate at which the infantry could advance. The infantry moved as close as possible to the wall of bursting shells, and were thus virtually subordinated to the artillery, being little better than mere "barrage-followers." The tactical low-level of the Somme was raised somewhat at Verdun in the autumn. Here, on Oct. 24 and Dec. 15, the French, under the direction of Gen. Nivelle and the executive command of Gen. Mangin, made two *ripostes* which achieved a high ratio of prisoners and ground captured at a most economical cost. The reason lay partly in exceptional staff-work, partly in a high concentration of artillery with a minimum of infantry, and partly in a greater elasticity of the limited objective attack with a creeping barrage.

#### IV. THE SURPRISE ATTACK

The chief tactical significance of 1916 lies, however, in the débüt of the tanks, in the Somme battle on Sept. 15. Contrary to the advice of their sponsors, the tanks were used in dribblets as soon as they were available, instead of being kept until a large quantity were ready to attempt a surprise on a large scale. As a result of minor technical faults and tactical mishandling they achieved only a limited, though promising, success. In a memorandum of Feb. 1916, Col. Swinton had outlined their correct employment and tactics, but nearly two years were to pass before this was put into practice, at Cambrai.

1917.—The opening of 1917 saw a reversion to the "break-through" idea. The contrast of the bright autumn successes at Verdun with the duller and slower progress, at heavy cost, on the Somme, had thrown the "limited objective" method into public disfavour! Joffre was superseded as Generalissimo by Nivelle, who, on the Aisne in April, tried to apply the Verdun method to a large-scale attempt to breach the German defences "at a rush." Its inherent fault was that the decisive blow was aimed before the enemy's reserves had been "fixed" or worn down. The experiment failed, and Nivelle gave way to Pétain. For the remainder of the year the British Army bore the brunt. The Battle of Arras showed little originality and the initial profit was squandered by continuing the offensive too long. The capture of the Messines ridge was a perfectly executed model of the "limited" method, but was only intended as a prelude to the offensive which began on July 31.

Tactically, this grim struggle is distinguished by two features. The first was a positive development in defensive tactics by the Germans, who based their resistance on a framework of machine guns in concrete pill-boxes, replacing quantity of man-power by

quantity of fire-power, and the old linear defence by a dispersed system of strong points disposed in great depth. The men, thus saved, from the wasteful rôle of acting as human stop-butts for the attacker's bombardment, were held in reserve and used for counter-attacks. Deserved success crowned the originality of this break-away from the pernicious idea of sacrificing men rather than lose a yard of ground, and the substitution of an elastic method, which by combining the principles of concentration and security was better economy of force.

The second feature was the negative lesson that the more prolonged the bombardment the more it stultified its own object, by rendering impassable the ground which the advance was to traverse. The bombardment destroyed the intricate drainage system of the Ypres area and so converted it into a swamp.

*Tanks.*—The outcome of this lesson was the new method initiated by the British in Nov. (see CAMBRAI, BATTLE OF), whereby the vital element of surprise was regained through the release of a swarm of tanks without a preparatory bombardment. If the astonishing initial success was not exploited, owing to lack of reserves, the Cambrai method supplied the long-sought key to the trench deadlock. Eight months were to pass, however, before the key was to be turned in the lock, and in the interval the tactical interest shifted to the German side.

*German Abandonment of the Mass Attack.*—With Russia out of the struggle, the German command sought a decision in the West before the swelling volume of American reinforcements could redress the balance, now against the Entente. Lacking tanks, Ludendorff was compelled to attempt a solution by the improved use of existing methods—wider frontages of attack, the prompt infusion of reserves, new infantry tactics, and an artillery preparation which should be short enough to ensure surprise but compensate its brevity by its intensity. The keynote of the new infantry tactics was infiltration and manoeuvre by the little dispersed groups of automatic riflemen and machine-gunners. Instead of thick lines breaking themselves against the defender's posts, these groups penetrated between and pushed rapidly on, while the "islets" of resistance, cut off from help by the advancing flood, were outflanked and reduced by fresh troops from the reserve. Instead of the old massed blow the object was rather the filtering of the attacking force into the enemy's defensive system, crumbling it away. The concentration of troops acted as a reservoir for supplying the multiple jets, not as a wave to sweep over the defence.

The first offensive was launched on a 47 m. front north and south of St. Quentin, on March 21, after an intense bombardment of only five hours, in which full use was made of gas and smoke-shell. The able organisation of the attack and the rapid infantry exploitation resulted in a real break-through. The assaulting divisions were only brought up the previous night, for secrecy, and a continuous "leap frogging" of reserve divisions through exhausted leading divisions maintained the momentum of the advance. But the new tactical doctrine of reinforcing along the line of least resistance led, as it happened, to an alteration in the strategical direction—towards Amiens, with the object of separating the British and French Armies. As it approached Amiens, the German flood lost impetus, largely through the difficulty of supply across the old Somme battlefields, which was accentuated by the harassing operations of the British aircraft. And, in face of stiffening resistance, the Germans made the mistake of prolonging the offensive—an unprofitable drain on their strength. (See GERMAN OFFENSIVE.)

On the Lys in April, the Aisne in May, the method was repeated, each time with brilliant tactical success but without attaining a strategic decision. The interval, both in time and space, was too great for one thrust to have a direct effect on the other. None of the thrusts had penetrated quite far enough to sever a vital artery, and this strategic failure left the Germans with a series of huge salients, difficult to feed, wasteful to hold, and inviting a convergent counter-stroke.

Ludendorff made his last attempt on both sides of Reims, July 15, but surprise was lacking. East of the town he was foiled by Gouraud's large-scale improvement on the method of elastic

defence, whereby the thinly held forward positions dislocated the attack, and the Germans arrived in face of the strong main position with their initial momentum spent. West of Reims their penetration across the Marne merely enmeshed them more deeply to their undoing, for on July 18 Foch's counter-stroke fell on the west flank, first, of the salient created by the April offensive. Here the Cambrai method was repeated, a surprise blow led by masses of tanks.

*Mobility Regained by the Allies.*—An even better example was to follow, on the Amiens front, Aug. 8, where Rawlinson's army effected both a strategical and a tactical surprise—by misleading ruses, consummate precautions to ensure secrecy, and the use of 456 tanks. This blow convinced the German command of the hopelessness of victory, and it now fell to Foch to convert this loss of hope into the conviction of defeat. The new grand tactical feature of the last phase (*see VICTORY, ADVANCE TO*) was what may be termed the fluidity of attack, in contradistinction, as it was a counter to the elastic method of defence. Each attack was broken off as soon as its initial impetus waned and each was so aimed as to pave the way for the next, at some other point; the blows were close enough in time and space to have a reaction on each other. By this means the defender's power of transferring reserves to menaced points was checked, as his balance of reserves was drained.

The progressive decline in the German resistance enabled this process to continue despite the diminution and ultimate disappearance of the Allies' slender stock of tanks. The trench deadlock had definitely collapsed, and in the mobile conditions thus recreated their infantry, developing the new tactics of infiltration and manoeuvre, were able to press back the German rearguards. The gradual slowing down of the advance was due, not to the resistance of the enemy, but to the difficulty of supply through the devastated zone, a defect inherent in lines of communication which depend on a fixed and prepared track. But at the moment when this problem became serious, Foch was ready to launch a decisive blow through Lorraine, and the Germans, stripped of reserves, capitulated. It deserves note, however, that the Allies were at no time on the verge of a strategic break-through. Infantry had not the rapidity of movement essential if retreat is to be converted into rout, cavalry had not the protection necessary to preserve their mobility, and tanks were still immature, even had they been available in adequate numbers.

*The Tank Plan for 1919.*—The tactical history of the World War is not complete without mention of an original move intended for the 1919 campaign if the War had continued. Reflection on the disaster of March 1918 suggested to Col. Fuller, chief general staff officer of the Tank Corps, that its extent was due far more to the breakdown of command and communication than to the collapse of the infantry resistance. He evolved a scheme to launch a fleet of light fast tanks, under cover of a general offensive, which should pass through the German defences, and, neglecting the fighting troops, aim direct for the command and communication centres in rear. These destroyed, it was calculated that the disorganisation and capitulation of the combatant units would follow. This plan, adopted by the Allied command for 1919, is of profound significance in taking a mental and moral instead of a physical target.

## V. POST-WAR TACTICS

With the coming of peace, war weariness and financial exhaustion paved the way for the inevitable reaction which has followed every great conflict. If there was some tendency towards greater density and linear formations, the reaction was far more marked in regard to the new arms which had been born during the conflict. National conditions also had an influence. The German Army was prohibited the use of tanks and aircraft, and so could do no more than study them theoretically. The French, still pre-occupied with a recurrence of the German menace, reconstructed their tactical doctrine strictly within the limits of their recent war experience. True, such outstanding personalities and profound thinkers as Foch and Buat Berat—post-War chief of the general staff—recognised the likely predominance of aircraft

and tanks, but immediate needs left no money for experiment, and thus while progressive in thought the French have been somewhat static in practice and design. In the United States, on the contrary, design has made greater progress than tactical thought. The British Army, influenced by the varied conditions and problems which face it in so scattered an empire, has treated trench-warfare as a phenomenon rather than a normal future condition, and has trained for open warfare. For several years, however, the higher command looked back to 1914 for its model, rather than forward in order to gauge the future.

*Growth of the Mechanical Army.*—While seeking to quicken action and infantry movement, and discarding much of the paraphernalia of trench-warfare—e.g., cable communication and mortars—it failed to recognise that the inherent check on mobility was the vulnerability of infantry and cavalry in face of modern weapons, as demonstrated from 1914 to 1918; also the slowness of infantry, accentuated to-day through the substitution of muscle-power by mechanical-power in other departments and through air attack. The tendency to regard tanks as a transitory device for trench-warfare soon passed, but the idea that they were a mere aid to infantry remained. In the last year or two, however, the arguments put forward by a small band of thinkers have gradually permeated the army, and coupled with technical development have brought it about that to-day Great Britain is making more progress than any other country towards a mechanised army. On the horizon lie perhaps complete tank armies, or rather fleets—for then would be reproduced on land many of the tactical conditions of naval warfare. But for the present the practical problem is to fit the tanks into the framework of tactics and readjust the rôles of the older arms accordingly.

*The New Functions of the Tank.*—The greatly increased speed of the latest tanks makes close co-operation between them and infantry impossible; as complete a violation of economy of force, indeed, as it would be to yoke a race horse to a cart horse. Throughout the World War, infantry was called, illogically, the decisive arm, yet in practice it was dependent, first on artillery, and later on tanks, in order to act at all. Now that tanks can no longer be used to bolster up this fiction, infantry must stand or fall on their own merits, and the whole theory of modern tactics must be recast.

History gives us the clue to the solution of this problem, for until modern fire-arms made mounted action impossible, cavalry was always the arm of decision and exploitation—because of its suitability for rapid out-flanking movements, the devastating momentum developed during its charge, and the demoralisation its furious onset inspired in exhausted or shaken troops. When its vulnerability nullified its battlefield mobility, and the cavalry charge disappeared, war became lopsided and the stalemates of modern times inevitable. Infantry aided by artillery could fix the enemy, disrupt and disorganise his screening forces, but there was no effective means of completing their efforts by a decisive blow such as cavalry had formerly delivered. This deadlock was broken by the coming of the tank, which through the protection afforded by armour gained scope for its mobility. The deduction is that tanks are the modern substitute for cavalry as an arm of decision and exploitation. They have their limitations—certain types of ground on which they are handicapped and certain defences against which they are helpless—but so had the cavalry of old. These qualities and limitations must be weighed and their tactical use decided accordingly, as was that of cavalry by the great captains.

*Infantry in the Mechanical Army.*—The tactical rôle of infantry needs to be readjusted similarly. Their qualities are their ability to make use of broken or close country to obtain cover, and to traverse ground which is too rugged or wooded for the other arms. Their limitations are their slowness and lack of direct protection, and the latter is accentuated by the fact that to-day, for mobile warfare, they can only count on a fraction of the artillery support they enjoyed in the World War. To cover the whole front with infantry, spread like butter on bread, irrespective of the type of ground, is no longer feasible. An advance over bare and flat country in face of machine guns is merely suicidal, and, instead,

infantry sectors of attack should be chosen with as much calculation as is given to the other arms. The "universality" of infantry action is as out of date as its decisiveness. When the tactical rôles of the different arms have been recast and fitted together, we shall have restored the lost balance between offensive power, protection and mobility—and thus have recreated a flexible instrument of generalship and the art of war. For in the years 1914–8 the tactical artist was supplanted by the machine-tender.

(B. H. L. H.)

**TAFT, LORADO** (1860– ), American sculptor (*see* 26.354) was elected to the National Academy in 1911. He was director of the American Federation of Arts from 1914 to 1917 and in the latter year was appointed a member of the Board of Art advisers for the State of Illinois. He received a silver medal at the Panama-Pacific Exposition, San Francisco, 1915. His later works include: "Black Hawk" (1912), figure of an American Indian, at Oregon, Ill.; Thatcher Memorial Fountain (1918), at Denver, Colo.; and "The Fountain of Time" (1920), at Chicago. In 1920 he published *Modern Tendencies in Sculpture*; and in 1924 a new edition of *The History of American Sculpture*.

**TAFT, WILLIAM HOWARD** (1857– ), 27th President of the United States (*see* 26.354), endeavoured in 1911 to secure reciprocity in tariffs with Canada. The measure was approved by the Congress of the United States, but in Canada it was defeated. Meanwhile wide public interest has been awakened in the conservation of national resources and the President's attitude was attacked by the Conservationists. In 1909 Gifford Pinchot, chief forester, charged Richard A. Ballinger, Secretary of the Interior, with being opposed to conservation. A Congressional committee, after investigation, exonerated the Secretary, but he later resigned. The attack upon Ballinger was denounced by the President, who continued to be criticised in connection with the sale of public lands, and who dismissed Pinchot from office. The President lost ground as a result of a breach of friendship between himself and Theodore Roosevelt, who supported Pinchot. In 1912 the President signed the Panama Tolls Bill, exempting American coastwise shipping from tolls, affirming that it did not violate the Hay-Pauncefote Treaty and that the United States had the right to fortify the canal. At the same time he expressed a readiness to arbitrate the question with Great Britain, who had protested.

Cleavage within the party was crystallised at the Republican National Convention in 1912. In the pre-convention campaign Roosevelt came forward as leader of the progressive wing against Taft as leader of the conservative or "stand-pat" wing, and the mutual recriminations were bitter. At the convention, however, the conservatives controlled the party machine, and the committee on credentials excluded the Roosevelt contesting delegates. Taft was renominated on the first ballot, receiving 561 votes, 21 more than the required majority. Roosevelt denounced the action of the convention and later was nominated by the newly formed National Progressive party. In the ensuing election Woodrow Wilson, the Democratic nominee, won an overwhelming victory, securing 435 electoral votes to 88 for Roosevelt and 8 for Taft. President Taft carried only two States, Utah and Vermont, and those only by small pluralities. The general feeling throughout the country was that President Taft had shown a lack of administrative firmness, his good nature having caused him to vacillate. On retiring from the presidency in 1913 he became Kent professor of law at Yale, but devoted much time to lecture engagements. In 1913 he was elected president of the American Bar Association, and in 1914 first president of the American Institute of Jurisprudence, organised to improve law and its administration.

After the outbreak of the World War in 1914 he supported President Wilson's strong stand for neutrality. In 1915 he approved the Army League's campaign for preparedness. He was an active promoter of the League to Enforce Peace, but after America's entrance into the War he argued that victory was necessary for attaining lasting peace. In 1918 he was appointed by the President a member of the National War Labour Board for arbitrating labour disputes during the War. In 1919 he en-

dorsed the Peace Treaty of Versailles, regarding its most important part to be the Covenant of the League of Nations. He spoke throughout the country on behalf of the league urging reservations if these would secure ratification. He supported Warren G. Harding, the Republican candidate for President in 1920. On June 30 1921 he was appointed by President Harding Chief Justice of the Supreme Court to succeed Edward Douglas White, deceased. An insistent advocate of legal reform, particularly in regard to the reorganisation of the Federal Courts, he also urged the appointment of additional judges and the provision of machinery for speeding up the procedure. He also drafted a code of canons of conduct for the guidance of the judiciary, which obtained the endorsement of the American Bar Association.

Taft was the author of *Popular Government: its Essence, its Performance, and its Perils* (1913); *The Anti-Trust Act and the Supreme Court* (1914); *The United States and Peace* (1914); *Ethics in Service*, Yale lectures (1915); *Our Chief Magistrate and His Powers*, Columbia lectures (1916) and *The Presidency: its Duties, its Powers, its Opportunities and its Limitations*, lectures at the University of Virginia (1916).

**TAGORE, SIR RABINDRANATH** (1861– ), Indian poet and author, was the youngest son of Maharshi Devendranath and grandson of Prince Dwarkanath Tagore. After a private education in India he was sent to England to study law, but soon returned to India, and while still quite young commenced writing for Bengali periodicals. In 1901 he established the famous Shantiniketan, or "abode of peace" at Bolpur, 93 m. from Calcutta, which developed into an important instructional institution. Originally organised as an *ashram*, or retreat, by the Maharshi, it was developed by Rabindranath into a school conducted on unconventional lines, and he aimed at enlarging it into an international university which should comprehend the whole range of Eastern culture. Rabindranath published some 30 poetical and 28 prose works in Bengali, many of which are regarded as classics. The more important of them were translated into English and gained a wide popularity. The author visited Europe on several occasions and travelled also in Japan and the United States. In 1913 he was awarded the Nobel prize for literature, and utilised the amount £8,000 for the up-keep of the school at Bolpur. He accepted a knighthood in 1915, but in 1919 resigned it as a protest against the methods adopted for the repression of disturbances in the Punjab. In later years, however, he offered no objection to the use of this title.

His volumes of poems, with the dates of their English translations include *Gitanjali* (1913); *The Crescent Moon* (1913); *The Gardener* (1913); *One Hundred Poems of Kabir* (1915); *Fruit-Gathering* (1916); *Stray Bird* (1917); *The Lover's Gift and Crossing* (1918). Among his novels are *The Home and the World* (1919); and *The Wreck* (1921). He also published several plays and volumes of short stories, letters and lectures. In 1917 appeared his *My Reminiscences*.

(F. H. B.)\*

**TAJIKISTAN** (*see* Tajik 26.365), an autonomous Socialist Soviet Republic within the territories of Uzbekistan. It lies to the north of the Oxus, opposite Badakshan in Afghanistan. (*See* TURKESTAN.)

**TANGANYIKA TERRITORY** (*see* GERMAN EAST AFRICA, 11.771).—During the World War German East Africa was conquered by British and Belgian troops. The mandate to administer the country was given in May 1919 by the Allied and Associated Powers to Great Britain, but by an agreement of Sept. 1919 between Great Britain and Belgium the mandate for Ruanda and Urundi, the northwestern parts of the former German colony, was transferred to Belgium, while Portugal was given the small area at the mouth of the Ruvuma river known as the Kionga triangle. The area of Tanganyika Territory is about 373,000 square miles. The population (1921) was approximately 4,107,000 natives, 2,400–2,500 Europeans, some 10,000 Indians and 4,000 Arabs. Ruanda-Urundi, with an area of about 20,000 sq. m. only had about 3,500,000 inhabitants. The three districts of Tanganyika Territory adjoining Ruanda-Urundi, namely Bukoba, Mwanza and Tabora, had over 1,500,000 inhabitants; the rest of the Territory is sparsely populated. The capital is Dar es Salaam (population 1921, about 25,000, including 555 Europeans).

#### POLITICAL HISTORY

The years immediately preceding the outbreak of the World War in 1914 had been a period of much administrative and commercial activity in German East Africa, the principal achievement being the completion in Feb. 1914 of the railway from Dar es Salaam to Kigoma-Ujiji on Lake Tanganyika. There was a flourishing European settlement in the Usambara Highlands and, as far as civil administration was concerned, the colony had become self-supporting. The budget for 1914-5, the last framed by the Germans, balanced revenue and expenditure at £1,023,000, with £165,000 as an imperial grant for military purposes. (The story of the military operations is told elsewhere, see EAST AFRICA.)

The British and Belgians established their own administrations in the districts they conquered. It was not until March 22 1921 that all the districts which Belgium had occupied but which fell within the British mandated area were transferred to Tanganyika Territory, the name officially given to the British area in Jan. 1920. A civil administration had been set up while the War was in progress, Mr. (afterwards Sir) Horace Byatt being the first administrator—a title changed in Aug. 1920 to that of governor. The country had suffered severely from the ravages of war and the work of reconstruction was difficult and prolonged. All the German settlers were repatriated and their estates sold. Up

to the end of 1924 these estates had realised £1,221,000. Until this process was nearing completion few new land grants were made and agriculture for a time was practically at a standstill. Moreover both the planters and the commercial community complained, with some show of reason, that the Government was indifferent to their needs. Complaint was also made by the Europeans of the competition of the Indians. As to that the administration was tied by the terms of the mandate (which were approved by the Council of the League on July 20 1922). The mandate enjoined equality of treatment to nationals of all members of the League in matters of "residence, trade and commerce." The administration was hampered by lack of funds and the necessity of rebuilding a large part of the Central Railway (the Dar es Salaam-Tanganyika line); and it had as its first duty the care of the natives, many of whom were restive and demoralised by the War. It had its hands full; nevertheless it might have paid greater attention to the needs of planters—and the Amani Institute for scientific research, which was one of the best works of the Germans, was allowed to go nearly to ruin.

In Nov. 1924 Sir Horace Byatt was transferred to Trinidad and Sir Donald Cameron succeeded him as governor of Tanganyika. Meanwhile attention had been called to the suitability of the highlands in the southwestern parts of the territory for white

settlement and a number of Europeans subsequently bought farms there. This region, however, lacked means of communication; to open it up, and at the same time to provide an outlet for the trade of northern Nyasaland and northeastern Rhodesia, it was decided in 1926 to build a railway crossing the highlands and extending to Lake Nyasa. The project to link up Uganda and Tanganyika by a railway had been abandoned. The only route for such a line was through a part of Ruanda, and that part had therefore been retained in British mandated territory by the 1919 agreement with Belgium. This arrangement had, however, led to a division of the native State of Ruanda and had caused inconvenience. By a new Anglo-Belgian agreement of 1923 the strip of Ruanda which had been in Tanganyika was assigned to Belgium. The connection of Lake Victoria with the Tanganyika system by a railway from Tabora to Mwanza was, however, decided upon in 1926.

The importance of Tanganyika as a vital link in the chain of territories in East Africa under British administration was clearly recognised by the Parliamentary Commission which visited East Africa in 1924. It was emphasised at an unofficial conference of delegates, representing the settlers of four territories interested, held in 1925 at Tukuyu (formerly Neu Langenburg) and at a conference of East African governors held at Nairobi in 1926. Both conferences were concerned principally with questions of economic development. Political federation was not favoured. By this time (1926) the era of transition after the War had ended and it was announced that Tanganyika would be given a legislative council. Ex-enemies were allowed to enter the Territory.

#### ECONOMIC CONDITIONS

Tanganyika depends mainly on agricultural and jungle produce. The considerable sylvan wealth is undeveloped and rubber has ceased to be exported. Gold is worked on a small scale and diamonds have been discovered near Mwanza. Mica, too, is worked—but the mineral resources of the territory were but partially known up to 1926.

Commercial depression and currency difficulties, the enforced change as in Kenya Colony (*q.v.*) from rupees at 15 to the £ to florins and then shillings, added to the cost of restoring the devastated regions, reacted unfavourably both on trade and revenue. The volume of trade increased however from £3,098,000 in 1922 to £5,451,000 in 1924. In the last-named year commercial imports were valued at £1,901,000 and exports at £2,695,000, while the transit trade, mainly with the Belgian Congo, was worth £693,000. Cotton-piece goods, foodstuffs and iron and steel manufactures were the chief imports. The principal exports were sisal (worth £644,000 in 1924), ground-nuts (£359,000), coffee (£352,000), cotton (£373,000), copra, hides, skins and grains. Ivory worth £120,000, gold valued at £30,000 and mica at £27,000 were exported in 1924. Nearly all the gold was alluvial, from the Lupa river washings. By 1925 trade had recovered to the level reached in 1913. Some 75% of the cotton was raised by natives.

Revenue increased from £669,000 in 1919–20 to £1,315,000 in 1923–24. Expenditure in the same period rose from £790,000 to £1,901,000. The bulk of the excess of expenditure was on railways. The deficit on the working of the railways had been reduced to £92,000 in 1923–4, as compared with £158,000 in 1919–20, while in 1925 the railways paid their way. The chief sources of revenue are the house, hut and poll tax and customs. About half the revenue in 1923–4 was paid by the natives.

**BIBLIOGRAPHY.**—*Report on Tanganyika Territory XXX to the End of 1920*, a British official publication (1921); subsequent Reports to the League of Nations (Geneva, annually), and the *Report of the East Africa Commission*, issued by the Colonial Office (London, 1925). The *South and East African Year Book and Guide* (London), and the *East African Red Book* (Nairobi) give useful information. For the Anglo-Belgian boundary see the *British Blue Book Correspondence Regarding the Modification of the Boundary XXX in East Africa* (1923). (F. R. C.)

**TANGIER** (see 26.397), a town and district of Morocco (*q.v.*) which enjoys a neutralised and internationalised régime under the sovereignty of the Sultan of Morocco. Its area is 200 sq. m.

and the population (1920) about 50,000 for the town and 70,000 for the town and district.

**History, 1911–23.**—The Franco-German crisis of 1911 which had threatened to disintegrate Morocco, if not to lead to an European War, left Tangier practically unaffected, and the Franco-German treaty which ensued included amongst its clauses the article which had appeared in every earlier treaty since 1904, that Tangier was to receive in due course of time a special régime. While in 1912 France and Spain began the occupation of their respective zones, not without recourse to arms, for the natives did not always acquiesce, Tangier remained a part and parcel of the old Morocco under the direct rule of the Sultan and his Maghzen, modified by a system of rights of intervention on the part of the European Representative.

The declaration of a French Protectorate over Morocco did not alter the situation at Tangier, which was understood to fall outside the effect of that declaration. If by this isolation Tangier escaped being drawn into the fighting which spasmodically occurred as the French and Spaniards advanced to occupy new districts of their zones, it suffered from the fact that, abandoned to a continuance of corrupt and unprogressive government, no amelioration in its situation was possible. The jealousies of the Powers and of their local representatives, the obstruction with which certain Governments never ceased to meet every proposition of progress, prevented Tangier from benefiting from its superb position and becoming a place of commercial and maritime importance. So loud grew the complaints of its population that the Governments of Great Britain, France and Spain decided in 1913 to draw up a convention and introduce the special régime which the treaties accorded.

After long months of negotiation the representatives of the three Powers concerned were on the point of signing the Convention in 1914, when the War broke out, and the Spanish Govt. refused to sign. No doubt Spain preferred to await the results of the War before she definitely signed away her hope of one day possessing Tangier herself. So the status remained unapplied and the Convention disappeared in the pigeon-holes of the Foreign Offices. Tangier's sufferings were thus prolonged and its fate left unsettled. The construction of the port which had been decided upon in 1910, when an international company was formed for that purpose, was again postponed and obstruction to progress and prosperity was once more the order of the day. While the towns of the Atlantic Coast, under the very able administration of Maréchal Lyautey, were becoming both large and prosperous, Tangier remained stationary.

Tangier, like the rest of Morocco, was little affected by the War. Food was plentiful, restrictions few. During that whole period there was but one incident of importance, the expulsion of the German and Austrian chargés d'affaires and the personnel of their Legations. The internationalisation of Tangier rendered it doubtful what steps the Allied Governments would take on this question, but the Sultan of Morocco, under whose direct jurisdiction Tangier lay, was himself an Ally and the Governments interested did not hesitate to act. At the conclusion of the War Europe was too occupied to give thought to Tangier and the policy of obstruction continued to the lasting detriment of the place. Peace was seldom disturbed, though the fighting in the neighbouring Spanish zone impeded trade and closed the roads.

**The Statute of 1923.**—It was not until 1923 that the question of Tangier's future was once more taken into active consideration. The situation had now changed. France's position had become stronger since the Sultan had recognised her protectorate. The British Govt. was, however, still determined that an international form of government must be adopted, and Spain, having failed to benefit by the War, supported this demand. It was a question difficult of solution and a preliminary conference in London in July 1923 failed to bring about any settlement. It served, however, as a useful exchange of views and in the following Oct. British and Spanish delegates proceeded to Paris where the negotiations were continued. On Dec. 18 1923 the Convention was signed by the representatives of France and Great Britain and on Feb. 7 1924 by Spain.

The new status of Tangier is based upon a charter of permanent neutral internationalisation, under the sovereignty of the Sultan of Morocco, who maintains his control over Moslem and Jewish Moroccan subjects. The Sultan is represented by a high Moorish official, the Mendoub. The administration of this town and its zone rests in the hands of an Administrator and two Assistant-Administrators, who carry out the decisions of the Legislative Assembly, subject to their ratification by the Committee of Control. The Convention laid down that during the first six years the Chief Administrator should be a French subject and his assistants a British and a Spanish subject. After that period they should be chosen by the Assembly. A French and a Spanish engineer should superintend the public works. The Committee of Control, consisting of the Consuls of all the Powers—except ex-enemy Powers—who signed the Algeiras Act has power, by majority decision, to veto the acts of the Legislative Assembly. The Legislative Assembly consists of 26 members, chosen from the subjects of the Powers represented in Tangier and from the Moorish and Jewish population. The number of members representing each nationality is regulated by the local importance in population, trade and influence of the nationality in question. Clauses have been introduced into the Convention and in the legal codes for progressive modifications at specified periods of time should modification be deemed necessary or advisable.

Special legal codes have been drawn up based on those in use in the French and Spanish zones. Justice is to be administered in mixed tribunals by judges of different nationalities. A gendarmerie of 250 men, natives of Morocco, is placed under the command of a Belgian captain with French and Spanish assistants. It is quite evident that such a scheme is far more difficult to put into practice than to put upon paper, and even two years after its signing in Paris the status had not become a going concern. Its initiation was rendered far more difficult than would otherwise have been the case by the refusal of Italy and the United States of America to accept the conditions it introduces, and by the delays of Portugal to adhere. A certain confusion resulted, for the dissenting Powers refused to allow the operation of its edicts upon their subjects. Consequently while the subjects of all the assenting Powers passed under this new régime, those of Italy, America and Portugal retained their old status, under which they were not legally bound to pay the new forms of taxation and other charges imposed upon the less fortunate subjects of the adhering Powers. (See also MOROCCO.)

**BIBLIOGRAPHY.**—Tangier Convention (Cmd. 2096, 2203); A. Cases, *Tanger, dignidad nacional* (Madrid, 1922); P. Champion, *Tanger, Fès et Meknès* (Paris, 1924). (W. B. H.)

**TANG SHAO-YI** (1858— ), Chinese statesman, a native of Kwantung, became notable as the first foreign-trained Chinese to rise to high office, and one of the leaders of the Chinese nationalist movement which adopted the cry of "China for the Chinese." He was educated in the United States at Columbia University and received his first important post in 1898, when he became consul-general in Seoul in succession to Yuan Shih-kai. Gaining the favour of that rising statesman, he was appointed director of the Northern Railway and customs Taotai, and undertook important missions to Tibet (1904) and India, the result of which was the Tibet Convention of 1906. His ability and friendship with Yuan Shih-kai brought him a number of lucrative posts, but his radical sympathies and progressive policy earned him the dislike of the reactionaries, and he was impeached on the grounds of "self-sufficiency and the employment of unsuitable persons." Recovering from this set-back, he was appointed special envoy to Europe and the United States (1908). He played an important part in the negotiations that followed the revolution of 1911, and in 1912, became Premier under Yuan Shih-kai. But in June of that year he fell, and though he held office several times during the succeeding decade, he never played the great rôle for which his ability once seemed to single him out. In 1919 he was one of the four directors of the Canton Govt. and was minister of finance at Canton 1919–22. Though a strong nationalist, Tang never showed hostility to foreigners, but, on the contrary, protected them at much risk during the Boxer rebellion (1900).

**TANKS.**—The name tank was given during the World War to the bullet-proof, armed vehicle, driven by mechanical power and capable of crossing rough country and obstacles by the use of caterpillar tracks. The name was first used in Dec. 1915 as a blind to conceal the true nature of the experimental fighting machine then being secretly constructed in England; after the first appearance of the machine in the field the name was universally adopted. To the British is due the credit of first conceiving and introducing this weapon which was destined to exert a decisive influence on the course of the War.

## I. THE INVENTION OF THE WEAPON

*The Tank Idea in History.*—From the earliest times men have attempted to find methods whereby they might move under some form of protection while they delivered blows at the enemy. Vehicles of many different types have been constructed throughout the ages with a view to solving these first principles of war and those vehicles were the forerunners of the tank. The earliest fighting vehicles of which there is a record, date back to 1200 B.C. when the Chinese made use of protected vehicles propelled by man or horse-power and to the use of war chariots by the Assyrians. In the 15th century the Tudor "war carts" appeared and fighting vehicles were constructed which were the exact counterpart of the modern tank except in motive power; and numerous examples of fighting vehicles appear throughout history, all aiming at the provision of mobile protection for the fighting man.

The introduction of rifled breech-loading firearms led to the disuse of all forms of fighting vehicle. The weight of armour which was necessary to provide protection was such that no armoured vehicle could be propelled across country by man-power or horse-power. The necessity for a fighting vehicle still existed and was in fact accentuated, especially with the introduction of the machine-gun; there was, however, at the time no apparent solution to the mechanical construction of such a vehicle. As time progressed two inventions were developed and it was the combination of these that led to the construction of the tank. The two inventions were the caterpillar track and the high-speed internal-combustion engine. The former enabled heavy vehicles to cross soft ground by the use of a track or endless belt so that the weight was distributed over a large area of ground; the latter provided a light compact power unit by means of which the vehicle could be propelled. The combination produced tractors such as the Holt, invented and in common use in America before the War. Between 1907 and 1914 several inventors suggested that tractors of this nature should be constructed and provided with armour for use as a fighting vehicle in war. No official action was, however, taken in this direction. The prevailing military opinion among all nations prior to 1914 was that any future war would be mainly a war of movement, and although it was realised that a frontal attack against a defensive position would be costly, it was considered that such an attack would be greatly assisted or even avoided entirely by envelopment or flank action.

The opening phases of the World War appeared to confirm these views, but in Sept. the Germans fell back and took up a defensive position on the Aisne and it was then that the great strength of modern field defences became apparent. The main source of strength of these defences lay in the machine-gun protected by an extensive use of barbed wire entanglements, and they proved to be impregnable to attack by troops, equipped as they were in 1914, without the most prodigal loss of life. The efforts of the British troops early in Oct. to outflank the Germans in the north, led to an extension of these defences right up to the sea. The Allies were then faced with a continuous defensive position without flanks that could be turned and they possessed no means of penetrating such defences. One solution of the difficulty appeared to be a large increase in the available artillery resources, particularly in the larger pieces and the provision of high-explosive shells. This solution was acted on at once and although no result could of course be expected for many months, it was hoped that sufficient artillery and ammunition would eventually be available to blast a way through the enemy defences and so re-establish the power of mobility.

*Col. Swinton's Proposal.*—Early in Oct. 1914 an officer of the Royal Engineers, Lt.-Col. (later Maj.-Gen.) E. D. Swinton, Royal Engineers, formed the opinion that a frontal assault against prepared positions, especially with limited artillery support, had become impossible, and that some form of power-driven protected machine which could traverse trenches and barbed wire was necessary to enable the attack to overcome the power of the defence. On Oct. 20 1914 Col. Swinton saw Col. (later Sir Maurice) Hankey, Secretary of the Committee of

Imperial Defence, and put forward his scheme which was briefly to develop the Holt tractor and produce a mobile armoured machine which should lead the assault and act as a machine-gun destroyer.

As a result of the interview described Col. Swinton took up the question with G.H.Q. in France and Col. Hankey put the idea before Lord Kitchener; but in neither case did it lead to any result. Col. Hankey however also submitted the scheme to the Prime Minister as Head of the Committee of Imperial Defence; and this reached Mr. Churchill who was already experimenting with armoured cars for the naval detachment of the Belgian coast. On Jan. 5/1915 Mr. Churchill wrote to the Prime Minister emphasising the importance of Col. Swinton's suggestion. This letter was sent to Lord Kitchener, and at the same time Col. Swinton called at the War Office to discuss his proposals. As a result the matter received some attention and a few trials were carried out, after which the whole question was dropped. In the meantime Mr. Churchill formed a committee at the Admiralty under the chairmanship of Mr. (later Sir) Tennyson d'Eyncourt, to investigate the problem. They carried out trials with large wheeled machines, coupled steamrollers, pedrail and caterpillar tractors, single and articulated, the underlying idea being the production of a machine for the conveyance of troops and not a machine-gun destroyer.

In the meantime Col. Swinton took his proposals to the commander-in-chief in France with the result that the specification

of labour and material owing to the great national effort to produce munitions of every kind.

*The First British Tanks.*—The Mark I. tank was built in two types, "male" and "female"; both types had "sponsons" mounted on the sides to carry the main armament. On the male tank this consisted of two 6-pdr. guns and on the female tank of four Vickers machine-guns. The idea was that the tanks would work in pairs, the male tank being more capable of dealing with defences behind brick walls or steel loophole plates and the female tank having greater man-killing fire power. The total number under construction was 150, half being males and half females. The Mark I. tank was 26 ft. long, weighed 28 tons and carried a crew of eight men. The maximum speed on the level was 4 m.p.h. and the tank could cross a trench 10 ft. wide. Reference has already been made to the track which was carried all round the tank; this track was driven from the engine through a two-speed gear-box (controlled by the driver) and then through a differential which carried a second gear box at each outer end of the half shafts. These secondary gears were operated by hand levers and necessitated a gearsman on each side of the tank in addition to the driver. From these the drive was carried by chain to the driving sprockets in rear. As the original idea of the inventors had been that the tank should be used as a surprise on a large front the armour was for most part only proof against ordinary rifle ammunition. It was realised that it might be necessary, as was indeed the case, to increase the thickness

FIG. 1.—Sectional view of Mark I. Tank (tail omitted).

of the type of machine required was sent to the War Office. By that time a joint naval and military committee had been formed and they were now able to work to a specification which detailed the military requirements. The result was the production—first of "Little Willie" which just failed to reach the standard required, and later of "Big Willie" or "Mother" as it was christened, which passed all tests at Hatfield on Feb. 2/1915. The chief point in the design, and on which it differed from other caterpillar machines, was its rhomboidal shape and all round track which were the invention of Lt. (later Lt.-Col.) W. G. Wilson, working in conjunction with Mr. (later Sir) W. Tritton. This machine, afterwards known as the Mark I. tank, was the prototype of all British machines used during the World War.

In the meantime normal trench warfare had been proceeding in France. The artillery had been considerably strengthened, but even then it was found at the battle of Loos that large numbers of enemy machine-guns would survive the heaviest bombardment and cause prohibitive casualties to the attacking infantry. G.H.Q. France therefore ordered 40<sup>3</sup> of these experimental tanks, and this number was increased by the War Office to 100 machines. A tank supply committee was formed under the Ministry of Munitions with Major (later Sir) Albert Stern as chairman. Orders were placed on Feb. 12 and production started at once with utmost secrecy, and under great difficulties

<sup>1</sup> The first order placed by the French Army Headquarters, without awaiting the construction of an experimental machine, was for 400 machines; and this was increased to 800 machines.

of the armour, in later models, to withstand armour-piercing bullets, when the enemy had had time to produce large quantities of these bullets. The male tank carried 324 rounds of 6-pdr. shell and 6,272 rounds of S.A.A. The female tank carried 31,232 rounds of S.A.A. Both types carried sufficient petrol for about 15 mi. on a cross-country course.

A feature of this tank was the tail which consisted of a pair of steel wheels hinged on to the back of the machine and pressed down on to the ground with powerful springs. The wheels could be steered from the driver's seat and in this way the tank could negotiate easy bends; the wheels improved the balance of the machine and also slightly increased the trench crossing capacity. In order to take a sharp bend or swing round on its own axis, the wheels were raised by a small hydraulic ram and secondary gears placed in neutral on one side of the tank. The power of the engine was then transmitted to one side only and the tank would take a sharp bend, or if a brake was applied on the same side as the gears were in neutral, then the tank would swing on its own axis.

In March 1916 a unit was formed to man these first tanks. For the purpose of secrecy the unit formed part of the Machine Gun Corps and was known as the Heavy Section, Machine Gun Corps. This name was later changed to Heavy Branch, Machine Gun Corps. The unit was commanded by Col. Swinton and contained sufficient personnel to man the 150 tanks under construction. The unit was organised in six companies of 25 tanks each. As soon as the tanks began to arrive from the contractors

the unit encamped at a secret area near Elvedon in Suffolk and started driving and gunnery practice.

## II. THE TANK IN ACTION

*First Engagement on the Somme.*—In the meantime the Somme offensive in France had come to a standstill. The right wing of the attack between the Somme and the Ancre which had met with some success at the start was definitely held up. The very heavy bombardments of the greatly increased artillery force had enabled the attackers to make some headway, but in the end the artillery fire had shelled away the barbed wire and replaced it by a worse obstacle, namely shell torn ground over which the infantry could only advance with difficulty, especially in wet weather. Moreover, this ground was quite impassable to transport and any question of pressing forward at some point where an attack had met with success was rendered impossible, as no ammunition or supplies could be sent up until new roads had been constructed. It was at this stage that it was decided to use the first two companies of tanks in an attempt to resuscitate the advance between the Somme and the Ancre. These two companies were accordingly sent to France at the end of August.

On Sept. 15 1916 the first tank attack took place. The IV. Army was to attack and advance on the line Morval, Les Boeufs, Guendecourt and Flers and the V. Army on the left of the IV. Army was to advance on Martinpuich and Courcellette. A total of 49 tanks were to be used, the majority with the IV. Army. They were to advance in small detachments of two or three machines against the enemy strong points. The general idea was that they should advance so as to reach the objectives just before the infantry. In some cases lanes were left in the artillery barrage up which the tanks were to advance ahead of the infantry. The tanks advanced at dawn in a slight mist and came as a complete surprise to the enemy; the results were, however, disappointing. The tanks had been constructed to traverse wide trenches, banks and barbed wire obstacles, but not the shell torn ground which was the result of prolonged bombardment on a small area. Of the 49 tanks which were employed, 32 reached the front line. Of these nine went ahead of the infantry and rendered valuable assistance; nine kept up or followed just behind and helped in reducing strong points where the enemy were still holding out. The remaining 14 broke down or sank and became ditched in the soft shell torn ground shortly after the battle had commenced. One tank in front of Flers gave remarkable assistance to the infantry and caused the surrender of 300 Germans. On Sept. 25 and 26, 13 tanks were employed on the same front and a few were employed later, on Nov. 13. In each case a large proportion of the tanks were unable to negotiate the shell torn ground, but those that did rendered valuable assistance to the infantry, causing heavy casualties and the surrender of a large number of Germans.

The employment of the tanks in Sept. 1916 was contrary to the views of those who had originated the arm and were responsible for its production. They considered that the tanks should be kept as a secret and used in large numbers as a surprise on a new portion of the front so as to give a chance of achieving decisive success. By using the tanks in small numbers a repetition was created of the error made by the Germans when they released gas on a small scale on April 22 1915. It was done in order to resuscitate the Somme offensive and raise the morale of the troops, but it is doubtful if the value so gained was equal to the loss of surprise in the use of a new weapon which it entailed. It did however prove that the tank was a very definite reply to the machine-gun and barbed wire and that infantry accompanied by tanks could attack defended positions with every prospect of success.

*Improved Types.*—As a result of these trials it was decided that the arm should be expanded to a force of 1,000 tanks. The tanks were not to be used again until the spring and the winter was to be spent in re-arming and training. The original six companies were expanded to nine battalions and the force in France was to become three brigades, of three battalions each, under the command of Lt.-Col. (afterwards Major-Gen.) H. J.

Elles, R.E. Each battalion was organised in three companies and one mobile workshop, and each company was composed of four sections of four tanks each.

Although France had asked for 1,000 tanks, the design of the tanks had not been settled. There was much discussion as to whether a completely new design should not be introduced; suggestions were made that a type with much wider tracks, or possibly equipped with more than one pair of tracks, should be tried. In the meantime 100 machines were ordered which were to be similar to the Mark I. machine, but with certain minor improvements. These were known as the Mark II. and Mark III. machines. Other than the obvious fact that tanks had difficulty in crossing the pulverised ground on the Somme which was covered with craters and shell holes, the only military lesson that had been learnt as regards tank construction was the fact that it was not worth while fitting the tail to the tank; owing to its vulnerability and complications, it was constantly out of action and was of little value. The Mark II. and III. machines were therefore both very similar to the Mark I., the main differences being the provision of stronger rollers, and stronger armour to withstand the armour-piercing bullets which the Germans would be fairly certain to use in the next battle.

In the meantime the authorities in England who were responsible for the production of tanks were becoming perturbed about the delay over a decision as to the design of tanks for the order of 1,000 machines. For the original idea of fighting a surprise battle on a new front the existing design was suitable, but to produce the ideal machine for traversing the shell torn ground of an old battlefield, a new and special design was necessary and this would mean a complete new series of experimental trials, involving much delay. It was not till the end of March, involving the loss of five valuable months, that a decision was reached and it was then decided that the 1,000 machines should be of a type known as the Mark IV. This type was again very similar to the Mark I., using the same engine and transmission and the same shape of hull. It included the minor improvements already incorporated in Marks II. and III. and in addition had sponsons which could swing into the body for travelling on a railway, and so saved the labour of detaching and remounting these heavy sponsons for every railway journey. Another feature of this tank was that it carried an unditching beam which could be fastened when required on to the tracks to extricate the tank from a ditch. The Mark IV. tank was the main machine used throughout 1917 and the early part of 1918.

The next action in which the tanks took part was the battle of Arras on April 9 in which the I., III. and V. Armies attacked with a view to penetrating the German defences and allowing an Army Corps and two cavalry divisions to break through. Only 60 tanks were available for this attack and they were again used in the minor rôle of assisting the infantry to "mop up" machine-gun nests and small posts that had been passed over by the artillery barrage and the assault of our leading troops. The tanks were of the Mark I., II. and III. pattern and some of them suffered heavily from armour-piercing bullets. In many cases the tanks rendered valuable assistance, overcoming enemy machine-guns and barbed wire with ease. Although there had been a heavy preliminary bombardment the ground was not torn up to the condition in which it had been on the Somme and the result was that comparatively few tanks became ditched and most of these were soon extricated. The cavalry were prevented from breaking through owing to the usual obstacles—barbed wire and machine-guns—the tanks being far too few in numbers and too dispersed to be able to keep up the pressure and assist in further operations. The lessons were the same as before, namely that tanks should not be dispersed, but used in large numbers and further that succeeding waves were necessary to keep up the pressure and achieve decisive results.

*Messines.*—The next attack was against the Messines-Wyt-schaete Ridge on June 7 in which 76 Mark IV. and 12 supply tanks were used. The latter were made from old converted Mark I. or II. tanks and were used to keep the fighting tanks supplied with petrol and ammunition—a need which had been

FIG. 1. British Mark I. Tank, with gun dismounted. FIG. 2. Allied Tank (known by British as Mark VIII., and by Americans as the Liberty Tank). FIG. 3. British Medium C Tank.

FIG. 4. Vickers Light Tank (Mark II.). FIG. 5. French Renault Tank.

much felt in former battles. The attack was in the nature of an assault in the old form of siege warfare. The result was a complete success in which the tanks only played a small part, though in a few individual cases they rendered valuable help. The ground was completely pulverised by the preliminary bombardment but very few tanks became ditched, mainly owing to the fact that there had been no rain for many weeks and that there had been time to make a close reconnaissance of the ground and pick out the best lines of advance for the tanks. After this attack the arm was renamed as the Tank Corps.

*Failure at Ypres.*—On July 31 the third battle of Ypres was launched. As the preliminary bombardment had been so successful at Messines it was decided again to use a long preliminary bombardment lasting 10 days. The danger of thus rendering the ground impassable to tanks, especially if it rained, was explained by those responsible for the action of tanks, but it was considered that the value of the bombardment more than balanced the possible loss of the use of tanks; this did not prove to be the case as the Germans adopted a defence distributed in depth which did much to discount the value of the bombardment. Unfortunately it rained on the first day of the battle and although the tanks rendered much assistance in individual cases during the early stages of the attack, the ground soon became quite impassable to tanks, and later it became impassable to infantry as well.

*Success at Cambrai.*—Although the failure of the tanks at the third battle of Ypres was through no fault of the officers and men and those who commanded them, it led to much discussion as to whether tanks should be retained at all. The Germans formed the opinion that the tank was practically useless, and many British officers held the same view. Fortunately this view was not unanimous and on Nov. 20 permission was obtained to launch an attack at Cambrai, in which the tanks were to be used in the way in which their originators had intended that they should be used. This was the turning point in the history of the Tank Corps. The action as fought was in almost every detail the execution of the plan put forward officially for the employment of the tanks by Col. Swinton in Feb. 1916, seven months before the first tank action. The attack was to be a complete surprise and no preliminary bombardment was to be used. Three brigades of tanks (nine battalions) were to take part with a total of 378 Mark IV. tanks and 98 administrative machines (see CAMBRAI).

The attack was launched at 6:20 A.M. in a slight fog, Maj.-Gen. Elles leading the attack in a vanguard tank with the centre division. The operation was a complete success; the enemy were taken absolutely by surprise and most of the infantry bolted or surrendered. Within 12 hrs. the infantry had advanced 12,000 yd. on a front of 13,000 with only 4,000 casualties. A similar penetration at Ypres had taken three months, with enormous loss of life and morale. The preliminary bombardment which had cost some £22,000,000 at Ypres was dispensed with and a further advantage was gained in that the roads had not been torn up with shell fire and were available for use almost at once. And this had been achieved by the Tank Corps using great mechanical power, but numbering only 4,000 of all ranks.

As regards tank design three main lessons were learnt from the battle of Cambrai. First of all the tanks required to be handier, and controlled by one man, without the assistance of any gearsmen, and to meet this requirement the Mark V. tank was produced. This design had been suggested but not accepted almost a year previously. Outwardly the tank had the same appearance as Marks I. to IV., but the engine and transmission were much improved. The engine developed more power and the steering was effected by using epicyclic gears on the transmission to each track; this was the best tank produced during the War. Then the difficulty of crossing the wide trenches of the Hindenburg line had been considerable, and a certain number of special long tanks were ordered for this purpose. These were made from Mark V. tanks by adding a section in the centre to obtain the required length, and were known as Mark V.\* tanks. Later an improved type was made with a more powerful engine

known as the Mark V.\*\* The third lesson was the necessity at times for a much more mobile tank for use beyond the main trench systems. These tanks would not need to cross wide trenches and hence they could be shorter and lighter and more mobile. One type, known as the whippet, had already been constructed experimentally. These lighter tanks became known as "medium" tanks, and the whippet was named the Medium Mark A.

*German Offensive of March 1918.*—The Tank Corps was now expanded to five brigades of 13 battalions with 320 Mark IV. machines and 50 Medium A. machines. During the winter of 1917-8 all units were training and being equipped with new tanks. No further offensive operations were in view and there ensued a period of preparation for the expected German attack in the spring of 1918. To assist in repelling such an attack the Tank Corps was distributed in detachments on a front of some 60 miles.

The attack was launched on March 21 and the Germans advanced rapidly. The tanks took part in many improvised attacks in attempting to stem the German advance. Some of these met with fair success and caused heavy casualties but the tanks were too few and too dispersed to make their real weight felt. It was during this retreat that the Medium A. tanks were first engaged in action and they met with considerable success, their additional mobility being of great assistance in this type of warfare. The attack fought itself to a standstill within a month, immobility being caused more by the difficulties of transport than by the resistance offered by the Allies. The supply of ammunition and food to the advanced German troops, especially where the lines of supply crossed the old battlefields, became exceedingly difficult, and it was at this stage that the necessity for some form of cross-country transport to enable an army to pursue across the devastated country left behind by the opposing force, began to be realised. The Tank Corps had already foreseen its own requirements by the provision of supply tanks and sledges drawn by tanks, and later by moving signalling equipment in special signal tanks. A small number of gun carrier tanks had also been constructed at an earlier date for the transport of the heavier guns and ammunition, though these had not been found very satisfactory mechanically. At a later date large numbers of tractors were ordered for every type of transport work, with the idea that at any rate a portion of the army could be made mobile and independent of made roads for its line of supply, but none of these were received before the date of the armistice.

In the meantime a reaction had set in as regards the estimated value of fighting tanks. The critics asserted that the battle of Cambrai could never be repeated and pointed to the lack of decisive results achieved by the tanks during the German advance. The proposed expansion of the Tank Corps was postponed and the existence of the corps seriously threatened. Fortunately the Mark V. tanks were now arriving at the rate of about 60 machines per week, and on July 4 one brigade of tanks equipped with these machines carried out a surprise attack on the Germans at Hamel in conjunction with the Australians. The attack was a complete success. The extra handiness and mobility of this machine enabled it to be used very effectively against machine-guns, many of which were crushed and rolled into the ground.

*The Triumph of the Tank.*—The great French victory of Soissons on July 18 1918 marked the turning point of the War; the victory was largely due to the use of French tanks employed in much the same way as the British had used their tanks at Cambrai. This was followed by the opening of the British strategic offensive on Aug. 8 with the battle of Amiens. In this attack the tank tactics were those of Cambrai modified by recent experience and adapted to the improved machines available. The attack was carried out by three army corps, a cavalry corps and 11 tank battalions; nine battalions were equipped with Mark V. tanks and the remainder with Medium A. tanks. For the first time since tanks had been used for an offensive it was possible to keep some in reserve and 42 tanks were kept in hand.

The attack was a complete success, the greatest penetration of the tanks being  $7\frac{1}{2}$  miles. The tanks continued in action till Aug. 11.

From that date until the Armistice tanks took part in every main attack and in no case, where tanks were properly employed in conjunction with the other arms, did the attack fail. During this period the tanks co-operated in the battles of Bapaume, Epehy, Cambrai, St. Quentin, the Selle and Mauberge. Tanks came to be looked upon as essential to the success of any attack, and in his final dispatch the commander-in-chief stated that the successful attacks which won great victories at Amiens and afterwards would have been impossible without tanks. The Germans also confessed that it was the tanks that had caused the downfall of their armies in the field. An expansion of the Tank Corps to 34 battalions had been sanctioned if the War continued into 1919, and the Ministry of Munitions in England had hoped to produce a total of 6,000 machines in 1919.

### III. FRENCH AND AMERICAN TANKS

*Independent Invention by the French.*—The French were faced with the same difficulty as the British in the early stages of the War, and their attacks were held up by machine-guns and barbed wire although they were often well supported by artillery using high-explosive shells. It was Col. (later Gen.) J. B. E. Estienne of the artillery who first perceived the necessity for some mechanical machine which could cross the trenches and barbed wire in the face of machine-gun fire, and when this officer saw the Holt caterpillar tractors at work behind the British front for hauling guns, it occurred to him that the solution might be found in an armoured caterpillar machine. On Dec. 1 1915 Col. Estienne put forward his idea officially to the French commander-in-chief and asked for an interview. Thus the ideas which had been thought out by the British originators in 1914 were reinvented separately and independently by the French in 1915. As the result of Col. Estienne's interview, 400 tanks were asked for and the design was to be prepared jointly between Col. Estienne and M. Brille of the Schneider Works. Later a further order for another 400 machines was placed with the St. Chamond Works.

In June 1916 French Headquarters received information from British G.H.Q. as to what was being done in England. Col. Estienne visited England and saw the Mark I tanks in training. He expressed the view that the two countries should collaborate as regards the production of tanks and that as the British had progressed with the design of a large heavy machine, the French might specialise with a light machine for more mobile warfare. Colonel Estienne was specially insistent in the view that neither country should forestall the other in the use of tanks, but that they should co-operate and launch a great offensive in which both British and French tanks might obtain full value from surprise.

*French Light and Medium Tanks.*—The first light tank was produced by the Renault firm in Nov. but the production of these small machines did not receive official support. The French classified their tanks as "chars d'assaut," as they were called, in three categories, and this classification was generally accepted. The light tanks were under 10 tons in weight and were to be transported over long distances in lorries. The medium tanks (St. Chamond and Schneider) weighed between 10 and 30 tons and could be transported by rail on ordinary trucks. The heavy tanks, of which the British Mark I. formed the only example at the time, were machines weighing over 30 tons and required special railway trucks for transport.

A training centre was now formed at Marly-le-Roi and later an additional centre was started at Champlieu. On Sept. 30, the artillery d'assaut, which was the counterpart to the British Tank Corps, was formed under the command of Colonel Estienne. The French medium tanks now began to arrive. The Schneider tank was six metres in length and driven by a 60 H.P. engine. It was armed with a short 75 mm. gun and two machine-guns. The St. Chamond tank was somewhat larger and heavier, being 8 metres in length and driven by an 80 H.P. engine through

a petrol-electric transmission. The armament was one 75 mm. gun and four machine-guns. Both machines differed radically from the British tank in that the track was not carried round the machine but consisted of the ordinary short type used on tractors. This resulted in the machines having very limited climbing power out of shell holes or craters. The artillery d'assaut was organised in "groupes"; each "groupe" had four batteries of four tanks each. The light Renault tank was used as a "command" tank and one was allotted to each "groupe."

The delivery of both types of tank was very slow and instead of 800 tanks being ready for the spring offensive in 1917 only 250 had been received. The result was that only 10 "groupes" were able to take part in Gen. Nivelle's offensive. The French high command had grave doubts whether to make use of so small a number of tanks, but eventually decided to do so. The offensive was unsuccessful and although the tanks did good work in isolated cases, the result was disappointing. The employment of tanks in this manner was a repetition of the mistakes made by the British. The attack was not launched as a surprise and the tanks were dispersed and used in small detachments. The tanks showed certain faults but mainly mechanical troubles that were already known. The main fault was lack of climbing power owing to the body projecting beyond the front end of the tracks.

*Success of the Renault Type.*—Between this date and the end of the year 1917, the French tanks were again used on several occasions with similar results. On Oct. 23, five "groupes" took part in the battle of La Malmaison and met with much success though the battle was not launched as a surprise and was preceded by an artillery bombardment. During this period much discussion took place and designs were prepared for improved medium tanks and for heavy tanks. Finally in Dec. 1917 it was decided to concentrate on the Renault light type; this was the machine that Col. Estienne had asked for in 1916. Some of these tanks were already on order but production had been very slow. In Jan. 1918 it was decided to increase the orders, to a total of 4,000 light tanks, of which 1,000 were to be ready by the end of March. The Renault tank was a small machine weighing  $6\frac{1}{2}$  tons. The length was four metres and in addition there was a short skid tail in rear to assist in trench crossing. It was driven by a 35 H.P. engine. There were two types, one being armed with a 37 mm. gun and the other with one machine-gun. The crew consisted only of two men, one driver and one gunner.

The French had hoped to use their tanks in mass in a great offensive in the spring or summer of 1918, but the German advance on March 21 upset all these plans. Instead the tanks were used piecemeal and in local counter-attacks to stem the German advance. In May and June tanks were used on occasions and the Renault tank made its first appearance in battle on the east of the Forest of Retz. During this time the Artillerie d'assaut was reorganising and rearming. On July 18, the battle of Soissons took place and the French tanks came into their own. It was in many ways a repetition of the battle of Cambrai but as the warfare had been of a semi-mobile nature for some months, the wide trenches of static warfare were non-existent. This suited the Renault tanks. The attack was launched as a surprise using a total of 120 medium tanks and 700 Renault tanks. The attack was a complete success and definitely established the value of the tank in the French Army. From that date until the Armistice, the French tanks—mainly Renault tanks—took part in practically every attack and contributed largely to the success of the final French offensive.

*American Tanks.*—The Americans were quick to grasp the great possibilities of tank action on the Western Front and this form of mechanical warfare appealed to their national characteristics. Officers were sent to study the employment of tanks and questions relating to their construction and design. As a result the Americans decided to adopt the British heavy type of tank and the French light type known as the Renault tank. In Dec. 1917 an allied commission was formed and it was decided to construct a tank known as the Allied tank; this was a heavy tank similar to the latest British type and was to be the Mark

VIII. tank for the British Army. It was designed to use the Liberty aero engine and was known in America as the Liberty tank. A factory was erected at Neuilly Pailleux which was eventually to be capable of constructing and assembling these tanks at the rate of 1,200 a month and the first 600 were to be used for equipping the first American tank units. A large constructional programme was also started in America to produce both this type and the French Renault tank. The first tanks of this type were not constructed until just after the end of the War, but several American tank units equipped with British and French tanks took part in the latter phases of the War and met with marked success. If the War had continued the American tanks would have come in with an overwhelming effect in 1919.

**Anti-Tank Defence.**—The Germans never made any attempt to construct tanks in large numbers, partly due to the restricted manufacturing power possessed by Germany compared with the Allies, and partly due to the comparative failure of the British tanks at Ypres in 1917. A rather clumsy type of heavy tank known as the A.V.V. was constructed in small numbers. These and a number of captured machines were formed into units and used in small numbers in a few isolated cases during 1918, but owing to the way in which they were employed and handled they met with little success.

On the other hand the Germans made continual attempts to introduce some form of anti-tank defence, but as the British tanks met with comparatively small success in the early stages, these measures were only developed half-heartedly. The first step was the introduction of armour-piercing bullets which was countered by the use of thicker armour on the Mark IV. tank. Next the Germans turned their attention to the employment of field guns specially allocated for anti-tank defence and often dug in or concealed in the forward areas. The employment of field guns in this way seriously depleted the power of the German artillery for other purposes, but they were meeting with considerable success until the introduction of the Mark V. tank, which, with its increasing mobility was able to reduce very largely the value of this field gun defence.

In addition the Germans often employed obstacles such as pits and barricades or mines. The former required a large amount of material and labour in construction, and could usually only be made in isolated places or in defiles, and did not seriously trouble the allied tanks. The latter were a source of danger to friend and foe, and required much time and material before a continuous line of minefield could be constructed. Although tanks were blown up in isolated cases by German mines the danger was never serious. The Allies made preparations to meet enemy tank attacks with field gun fire and in some cases by the use of male tanks kept in hand for this purpose. The latter is the most certain method of secure defence against tanks but was never adopted by the Germans. In 1918 the Germans evolved a heavy anti-tank rifle which was capable of penetrating the armour plates of the tanks, but the rifle had a heavy recoil and was difficult to handle and did not prove successful as an anti-tank measure.

After the success of the Allies at the battles of Soissons and Amiens in July and Aug. 1918 the Germans were awakened to the great danger in which they stood from tank attacks. They then constructed a heavy machine-gun firing a 13 mm. bullet and capable of penetrating 30 mm. of armour. The gun was known as the Tuf, and great efforts were made to construct it rapidly and secretly, but none were ready till after the Armistice. The Allies knew of the construction of these guns and realised the value which they would possess for frontal defence. They hoped however that the increased mobility of at any rate a proportion of the tanks in 1919 would enable them to penetrate and attack the enemy in the rear or along his communication and thus discount to a large degree the increased defensive power of the Germans against a frontal attack by tanks.

#### IV. PROGRESS SINCE THE WORLD WAR

Since the War progress has followed similar lines. Some nations have adopted a special anti-tank gun and others a heavy

machine-gun but the most secure method is still the employment of some form of gun on a vehicle which can travel cross-country, and this in effect becomes a tank, though it may be a tank specially designed as a tank destroyer.

**Experimental Patterns.**—With the exception of the Germans, who are prohibited by the Peace Treaty from doing so, all great nations now employ tanks as part of their military force. The French have retained the Renault tank as the main armament of their tank corps and although they have carried out much experimental work with heavier tanks, no models have been considered sufficiently advanced to standardise and construct in any large numbers. The Americans have also constructed many experimental patterns but have retained the Mark VIII. or Allied tank as the heavy tank with which their tank units are equipped and the Renault as the light tank.

The British, as the originators of the tank, have made great efforts to maintain their lead. Some months before the conclusion of the World War, when preparations were being considered for a great offensive in 1919, the specification was drawn up for a tank which was to be a great advance on the existing patterns. It was to have a speed of 20 m.p.h. and be capable of floating and propelling itself across water. Enough petrol was to be carried to travel 200 m. cross country and the tank was to be long enough to cross a trench 12 ft. wide. This tank was to be used for attacking the enemy communications and headquarters while the more conventional tanks were attacking the main armies in front. The first experimental model was actually completed just after the Armistice. The tank used a system of spring suspension on a cable and hydraulic power for control. Although the machine attained a speed of 28 m.p.h. and swam successfully across a narrow river on several occasions, it proved to be unreliable owing to the many new devices which it contained and which required further development. The next step that was tried was to produce a machine with an improved form of steering. Up till then tanks had been steered by locking one track and skidding round to the desired direction. This method of steering absorbs a large amount of power and brings large and unnecessary strains on the track and transmission. The device now tried was to produce a track with lateral flexibility so that it could be laid in a curve and enable a tank to take ordinary curves in the same way as any other vehicle. The problem however was found to present many mechanical difficulties and, although much work has been done, no satisfactory solution has yet been found as far as tank construction is concerned.

**The Vickers Light Tank.**—In the meantime the British Tank Corps which was reduced to four battalions after the War, was armed with the Mark V. tank and the Medium C. The Medium B. replaced the Medium A. at the end of the War, but very few of this model were made and the units were equipped with an improved type in the Medium C. This machine had a maximum speed of 12 m.p.h. and a radius of action of 70 m. and would have been a very useful tank in France. But by 1920-1 these machines were becoming worn out, and, although much knowledge had been gained, the experimental machines aiming at far higher achievements, and which have already been referred to, were not yet in a satisfactory state for production. A tank was therefore designed which was constructed on conventional lines and aimed at obtaining a high degree of mobility, if necessary at the expense of trench spanning capacity. The machine was known as the Vickers light tank. It is 18 ft. in length and weighs 10 tons and is armed with one 3 pdr. gun and two machine-guns. It can attain a speed of 20 m.p.h. and travel 150 m. on the petrol that it carries. Owing to its short length the tank has poor obstacle-crossing capacity, but in other respects it has proved very satisfactory.

**The Future of the Tank.**—Since the War there has been much discussion on the subject of mechanical warfare, initiated mainly by books and essays written by Col. J. F. C. Fuller<sup>1</sup> who acted as General Staff Officer to the Tank Corps in France. The great

<sup>1</sup> These include *Tanks in the Great War*, *The Reformation of War* and the Gold Medal prize essay for 1919 in the *Jour. of the R.U.S.I.*, May 1920.

saving in man power that can be effected by using mechanical power instead of men and horses for transport purposes is now fully realised. Reference has already been made to the necessity of using tractors to render an army capable of cross country movement independently of roads and much has already been done in mechanicalising the transport of artillery in the British service. A detailed consideration of this subject is, however, beyond the scope of an article on tanks. More recently attempts have been made to produce a force composed of infantry, tanks and artillery, the whole force being capable of moving 100 m. in 24 hours by means of mechanical power. Such a force would have a value in war far beyond its numerical strength in men. Preliminary trials of this nature have already been carried out on manoeuvres in England but the whole subject is at present in its infancy.

More recently experiments have been carried out in England with very small tanks with a crew of either one or two men only. The one man tank<sup>1</sup> is constructed from the type of engine and transmission in normal commercial use and the tank is therefore both cheap and easy to obtain in large numbers for war. The control is so arranged that one man can fire the machine-gun at the same time that he is driving the tank. Tactically the object of employing such small tanks is twofold. In the first place they are required for scouting and reconnaissance duties. A commander who uses ordinary tanks for such purposes risks losing his tanks on minor enterprises before the main battle takes place; on the other hand infantry are slow in performing these duties and cavalry are often too vulnerable. The small cheap tank possesses none of these disadvantages. The second object is to obtain increased safety against anti-tank fire by the use of dispersion. As many as 20 of these small machines can be provided for the cost of one large tank, and by the use of large numbers it should be possible to advance in the face of anti-tank fire where a small number of large machines would fall an easy prey. These small tanks are capable of traversing any ordinary country at an average speed of 10 m.p.h. and can cross a trench about 4 ft. 6 in. wide. If warfare continues to be a serious possibility between great nations in the future, the development of great tank armies is certain. Heavily armoured tanks carrying large calibre guns will be the main arm in the battle, and these will be assisted by larger numbers of small tanks for reconnaissance and protective purposes. In addition there will be the administrative tanks or tractors for communications, engineer work and supply purposes.

See D. G. Browne, *The Tank in Action* (1920); E. G. Beck, *Tank Construction*, etc. (1921). (G. le Q. M.)

**TANNENBERG, BATTLE OF.**—No portion of the earth's surface has been more fought over than East Prussia. It was in 1410, on the field of Tannenberg, that the Teutonic knights were utterly routed by their enemies the Poles and Lithuanians, and German victory of 500 years later was in some degree the reversal of this defeat.

### I. THE GENERAL SITUATION IN AUGUST 1914

The Tannenberg of 1914 was the greatest victory achieved by any of the combatants at the commencement of the World War, and its strategic and moral effect upon the succeeding years of the struggle were far-reaching. France and Russia had been joined by military convention since 1892 and their Chiefs of Staff had made careful arrangements for concerted action. In case of war with Central Powers it had been agreed that Germany was the main enemy and that the principal military effort must be made against her. She was to be attacked in East and West as nearly simultaneously as possible, so that she might not be in a position to reap the advantage of her central situation. Her preparedness and offensive military spirit made it tolerably certain that she would attack France first, leaving her ally Austria to hold Russia in check, until troops from the West could be made ready to crush Russia in her turn also.

<sup>1</sup> The inventor of this new machine which, if its promise matures, may be epoch making, is Major Martel.—(Ed. E.B.)

Owing to the vastness of her territory and to the comparatively undeveloped state of her railways, Russia's rate of concentration was considerably slower than that of France, so much so that there was a danger of the latter being crushed before the attack on Germany in the East could commence to exert its effect. Unfortunately, under the pressure of French insistence, the good will and optimism of Russia's military leaders exceeded practical possibilities and the outbreak of war found her military plans in some disorder. Austria was regarded by the mass of the Russian people as the main enemy, for it was she who had attempted to drag on the Southern Slavs, and the Russian General Staff found themselves unable to alter their main advance to one against Germany. All their initial operations in East Prussia were in fact hasty improvisations.

Geographically, East Prussia points forward into the heart of Slavdom and constituted a difficult problem of defence for Germany. True to her policy of concentration of force at the decisive point, she had decided to advance against France with her main forces whilst maintaining only a minimum of strength in the East. Not wishing to abandon national territory without a blow, she had decided to concentrate this minimum strength in East Prussia, despite the dangers involved in such action. Germany's strength in the East was to consist of 11 divisions, six first-line and five second-line, with but a single cavalry division.

Taking the East Prussian front as it appeared to the Russians, we can divide it militarily as follows:—

(a) *Königsberg Area.*—A more or less fortified area extending over the Königsberg peninsula, of a depth of 19 m. from north to south. In the centre lay the obsolete fortress, strong against anything but heavy artillery. The area could be reinforced by sea through the canal from Pillau. It formed a strong flanking position from which to attack any force attempting to pass it to the south.

(b) *Insternburg Gap.*—A gap of 43 m. of open country, down which ran the main Insternburg-Allenstein railway. The River Angerapp running north and south blocks this gap. It formed an excellent line of defence with the right flank resting against the impassable Lake Mauer.

(c) *Masurian Lakes.*—A line of continuous lakes from Angerburg to the Russian frontier at Johannsburg, a distance of 50 miles. The narrow gaps between the lakes could be held with few troops, and the whole line presented an almost impregnable front behind which the Germans could operate to either flank.

(d) *Johannsburg-Działdowo (Soldau) Front.*—A distance of 75 m. running east and west. On the Russian side the country had been left a desert as a defence against Germany.

## II. THE RUSSIAN PLAN OF INVASION

The Russian plan for the invasion of East Prussia was to advance with two armies north and south of the line of lakes, with the object of enveloping the German forces supposedly concentrating behind this line. The northern army under Rennenkampf was to advance first, towards the Insterburg gap, with the object of drawing the Germans as far to the east as possible. The southern army under Samsonov was to advance to the line Rastenburg-Allenstein, with the object of striking the rear of the Germans opposing Rennenkampf.

Rennenkampf's army crossed the frontier on Aug. 17 with a strength of  $6\frac{1}{2}$  divisions and  $5\frac{1}{2}$  cavalry divisions. On the 20th an action was fought with the German VIII. Army at Gumbinnen. Von Prittwitz, the German commander in the East, had concentrated his main strength to meet Rennenkampf, six divisions and a cavalry division, whilst leaving some two divisions to face Samsonov's army, which was concentrating on the River Narew but was not considered to be ready to advance.

Rennenkampf had moved off without a great portion of his transport and found himself forced to halt on the 20th. Prittwitz advanced to attack him. There were serious miscalculations in the German movements, with the result that the action was indecisive, both sides suffering heavy losses. That evening the news arrived that Samsonov had not only started to advance, but that two of his corps were already close to the frontier and that he had at least five corps with him. The German commander abandoned all hope of defeating Rennenkampf on the 21st and ordered a withdrawal to the Vistula. He and his Chief of Staff were at once superseded.

*Hindenburg Takes Command.*—The new commander, Hindenburg, had not yet been employed in the War. His Chief of Staff, Ludendorff, reached Supreme Headquarters at Coblenz on the 22nd and the situation in the East was explained to him. He immediately ordered the troops retreating in front of Rennenkampf to halt at once and to prevent him from pursuing, and issued instructions for a concentration against Samsonov. General Hindenburg joined Ludendorff's train at Hanover and took over the command in this area at Marienburg on the afternoon of the 23rd.

Luckily for the new command, Hoffmann, the chief of the operations section under Prittwitz, had already carried out many steps facilitating the concentration desired by Ludendorff, and the situation, though alarming, had not grown worse since the supersession of Prittwitz. Samsonov's right was indeed well over the frontier near Ortelsburg and his left between Neidenburg and Działdowo (Soldau) but the Russian advance appeared to be slowing up. The German XX. Corps had taken up a position north of Neidenburg and was awaiting attack. The leading units of the I. Corps were detraining south of Deutsch Eylau and were moving up on the right of the XX. Corps. The 3rd Res. division had detrained at Allenstein and was moving up on the left of the XX. Corps. A Landwehr division and units from the Vistula garrison troops were also coming up. Thus, a strength of about six or seven divisions had been collected to oppose 10 divisions and three Cavalry divisions of Samsonov's army.

No decisive results could be expected from such strength, and decisive operations were the Germans' only hope. The most important feature of the situation, however, was that Rennenkampf had made no forward move since Gumbinnen and had lost all touch with the enemy in front of him. Ludendorff therefore conceived the idea of withdrawing all the troops from Rennenkampf's front, with the exception of the cavalry division, and of directing them against the right flank of Samsonov's army. Another four divisions thus obtained would give him an actual superiority over Samsonov and the direction of their attack might indeed be decisive.

## III. AN ACCOUNT OF THE BATTLE

Samsonov, who in peace time was the Governor-General of Turkistan, had arrived from sick-leave in the Caucasus on Aug. 12. He had seen neither his subordinate generals nor his staff before, and his immediate superior Jilinsky, the commander

of the northwestern front, was urging him forward to cross the frontier on the 19th. The original concentration areas of his army behind the Bobr and the Narew had been considered to be too far to the east and a general move of all corps to the west was in progress. By the 20th, the right wing (VI. and XIII. Corps) had reached the frontier, with the 4th Cav. Div. well behind on the right. The left wing (XV. and I. Corps) was just short of the frontier, with the 6th and 15th Cav. Divs. covering it. Of the XXIII. Corps, one division was two days' march behind the left wing and the other had not yet detrained at Warsaw. The troops had been marching for a week across the desert area north of Ostroleka, over execrable roads in very hot weather. Much of the transport had been left behind, the men were tired and unfed and numbers had been much reduced by sickness. No contact had been gained with the enemy and the army was already more than 24 hours late in crossing the frontier. Reports from Rennenkampf of his victory at Gumbinnen and, during his advance westwards on the 24th and 25th, of the signs of a hurried retreat on the part of the Germans, brought further urgings from Jilinsky to Samsonov to hurry. Samsonov obeyed to the best of his ability, and by the morning of the 26th his position was as follows:—

His centre of two corps (XIII. and XV.) was advancing north-west and was close on the line Allenstein-Hohenstein. On his right was one corps (VI.) and the 4th Cav. Div. at Rothfließ, at two days' march from the centre. On his left was a corps (I.) and the 6th and 15th Cav. Divs. near Koschlau, at one day's march from his centre. The XXIII. Corps troops which were up were moving into the gap between the centre and the left. His forces were thus much dispersed.

Reconnaissance had been bad and he had little information as to the enemy's dispositions. He seems to have thought that the Germans flying in front of Rennenkampf had already crossed his front in their march to the Vistula and that he was too late to cut them off. He had deviated from his instructions to advance with his left on Allenstein and now had practically the whole of his force to the west of that town. He had no knowledge of the whereabouts of Rennenkampf's army and did not realise that he was increasing the space between the two Russian armies and thereby facilitating the German operations. His supply system had broken down utterly and his men were half-famished and worn out with the fatigue of excessive marching. The signal service had also broken down and orders had been sent out to corps by wireless. The Russian signals were easily read by the Germans, who thus had absolutely accurate information as to their opponent's dispositions and intentions.

*Germans Attack Samsonov.*—The new German Command had galvanised the dispirited VIII. Army from the first and hope of success ran high. The attacks on Samsonov's two flanks were to be launched simultaneously on the 26th. On the right, the German I. Corps, strengthened by the Vistula garrisons, attacked only half-heartedly. Von François, the commander of the I. Corps, was short of some of his heavy artillery and he contented himself with driving in some of the Russian outposts. On the 27th, however, he launched his attack in earnest. At dawn a hurricane bombardment was opened on the Russian I. Corps' positions on either side of Uzdowo. The famished Russians did not wait for the infantry attack but broke and ran. By 10 P.M. that night there was nothing left of the Russian left wing except a small rear-guard just north of Działdowo; and that too had disappeared before the next morning.

The rear of the Russian centre was now completely exposed and François directed his march on Neidenburg. Opposition there was none, and by the night of the 28th his leading troops had reached Muschaken, eight miles east of Neidenburg. By the night of the 29th the whole length of the road from Neidenburg to Willenberg was held by a line of entrenched pickets. The Russian retreat to the south was completely blocked. During the 30th François was attacked at Neidenburg by fresh Russian troops coming up from Miawa and actually lost the town for a time. He held stoutly on to the line of his pickets, however, and on the 31st Neidenburg was reoccupied.

On the left, the German XVII. and I. Res. Corps, having turned their backs on *Rennenkampf* and marched due south, had arrived within striking distance of the Russian right at *Rothfless* on the night of the 25th. Their attack on the morning of the 26th came as a complete surprise. The Russian VI. Corps withdrew in confusion, losing 6,000 men and 16 guns. By the night of the 27th the Russian right was 32 m. to the south of *Rothfless* and in a state of hopeless demoralisation. The rear of the Russian centre was now exposed on its other flank. The German XVII. Corps continued its march to the south, whilst the I. Res. Corps moved in closer towards *Allenstein*. The story of the fighting in the Russian centre is not so inglorious as that on the two flanks. In accordance with *Samsonov's* plan the centre (XIII. and XV. Corps) continued their advance on the 26th towards the line *Allenstein-Hohenstein*. The XIII. Corps encountered no opposition, but the XV. had to fight its way steadily forward. For the 27th, the advance was to be continued.

*Second German Blow.*—*Ludendorff*, with his accurate information of the events on either flank, now decided that the German centre had retired enough. The reinforced XX. Corps was therefore ordered to attack on the 27th. The battle which ensued between the Russian XV. Corps and the German XX. Corps was particularly fierce, the Russians holding their own and even advancing a little on their left. The Russian XIII. Corps rendered no help to its neighbour. On the 28th the Germans renewed their attacks and this time the hardy-ried Russian XV. Corps commenced to break. The XIII. Corps, moving down to assist, found itself assailed in rear by troops arriving from *Allenstein* and for the second time brought no help.

When night fell the two Russian Corps were on a line from *Grieslienen* to *Waplitz* and in close touch with the Germans. Hoping to escape from pursuit, they commenced to withdraw during the night. The withdrawal soon became a rout, and a mass of troops and transport, both unfed and unwatered, became inextricably mixed in the depths of the Forest of *Grünflies*. Determined attempts were made during the 29th to break through to the south of *Muschaken* and to the north at *Kaltenborn*, but the German ring held fast. Only some 2,000 men effected their escape. The greater portion of these two corps surrendered to the German parties, clearing the forest during the 30th and 31st.

*The End of Samsonov.*—*Samsonov* himself had moved up to *Neidenburg* on the 27th in order better to control the battle. He was greeted with the news of the disaster to both his flanks and met streams of stragglers coming into the town. He decided to go to the headquarters of the XV. Corps and take personal charge, and left *Neidenburg* on the morning of the 28th with a small staff, all mounted on horses. At once he became mixed in the mass of transport in the forest and could exercise no effective command. He then decided to ride to the south, but during the night of the 28-29th he became exhausted after having walked for some distance. He drew aside in the darkness and his staff heard a single shot. A careful search brought no result and the staff continued their way, certain that their unfortunate commander had taken his own life in his despair at the turn which events had taken.

*Results of the Battle.*—The practical result of the fighting from Aug. 26-30 was the total annihilation of two Russian corps and the reduction of three other corps to half their strength in numbers. The whole Russian II. Army was so demoralised and was so deficient in essential material, such as artillery and transport, that it was no longer of any fighting value. The Germans claimed 125,000 prisoners and 500 guns. It is certain that their booty was very great, for 60 train loads of captured material left *Puchallowen* after the battle and the captured horses were driven in herds to improvised camps at *Neidenburg*. Although greatly inferior in the whole Eastern theatre, the Germans had yet managed to concentrate a superiority on the field of battle. The Russians had 132 battalions, 96 squadrons and 620 guns, including 12 heavy, whilst the Germans had 155 battalions, 48 squadrons and 818 guns, including 128 heavy.

Ludendorff, My War Memories* (1922); *J. Daniloff, Russland im Weltkrieg, 1914-5* (1925). (See also *WORLD WAR: BIBLIOGRAPHY.*) (W. E. I.)

**TAOISM** (see 26.402).—The term Taoism has two meanings: (1) the philosophical system attributed to *Lao Tze* (b.604 B.C.) and *Chuang Tza* (b.330 B.C.); (2) the popular religion of the Chinese.

*Taoism as a Philosophical System.*—The term *Tao* originally meant the revolution or the way of the heavens about the earth. This movement of the heavens was regarded as the cause of the phenomena on earth. The *Tao* was located about the celestial pole which was considered to be the seat of power because all revolves about it. In the course of time this concrete expression became abstract, and the *Tao* was viewed as the universal cosmic energy behind the visible order of nature. This cosmic energy (see *CONFUCIANISM*) regarded as *being* is impersonal, omnipresent and eternal; viewed as *becoming* it works spontaneously, orderly, unselfishly and continuously for the highest good of all beings.

The *Tao* produced the *yin* and the *yang*, the negative and the positive principles of nature. These by their interaction brought forth heaven and earth. Heaven and earth gave birth to all beings. The human order is the product of the eternal energy.

*Philosophic Aspect.*—Taoism has usually been regarded as a mystic religion, but it was also an economic and political philosophy. It advocated frugality, simplicity and the joys of the peasant life in contact with the soil. It opposed the educational programme of the Confucianists, and advocated the theory that the people should be kept in innocence (not in ignorance). The Taoist philosophy is responsible for that remarkable trait of the Chinese, namely, their contentment in situations which offer a minimum of comfort, and their prizing of culture above possession.

*Political Aspect.*—In politics Taoism opposed a highly centralised government and favoured the maximum autonomy for the people. *Lao Tze* and his successors promoted the small village state which enjoyed full autonomy and lived in harmony with its neighbours. All forms of bondage and legal restraints were opposed. Non-resistance was exalted and militarism was condemned.

The ethics of Confucianism met with the strongest opposition on the part of the Taoists. Such virtues as love, justice, reverence, wisdom and sincerity were regarded as the first steps departing from the harmony of the simple life in the *Tao*, and producing the distracting contraries which marred the purity of life.

The Taoists were mystics, but they were practical mystics, who hoped to realise the best social order through a harmonious relationship with the *Tao*. Their ideal was "this worldly." Their mysticism had three stages: (1) the purgation, casting out selfishness and self-seeking; (2) union with the *Tao*, by which the individual lost his individuality with the distraction of the contraries; (3) power, which enabled the individual merged with the *Tao* to escape the limitations of time and space.

*Taoism as a Religion.*—Taoism as a religion is inherent in Taoism as a philosophy. The early mystics practised breathing and abstaining from food, and sought longevity and a future life in the Taoist paradise. The religious aspect did not become prominent, however, until the Han dynasty (206 B.C.-221 A.D.), when the Taoists occupied themselves in compounding the elixir of life and in making journeys to the Isles of the Immortals. They also developed several sects which practised exorcism and fortune-telling and exercised considerable political power.

The rise of Taoism as a church is attributed to *Chang Tao-ling* (b.34 A.D.), who developed a high degree of magic power which he transmitted to his heirs, together with the political prestige which reputation for such power brought. These took part in a successful rebellion in the latter part of the 2nd century, and established a state in *Szechwan* based on Taoist principles. The descendants of *Chang Tao-ling* were recognised by the Government and in 1016 were given a fief at *Lung Hu Shan* in *Kiangsi*.

Their function consisted of a general oversight of the Taoist priests and monks and the rule over the world of the gods. The system developed a hierarchy among the gods which corresponded to that of the Govt. of China. At the head was Yü Huang Shangti, the Pearly Emperor, who presided over an elaborate pantheon.

**Buddhist Influence.**—Through contact with Buddhism in the first six centuries of our era the Taoists appropriated the Buddhist world view, adopted the monastic system and imitated the Buddhist pantheon. Lao Tze was deified and was associated with Pan Ku and Yü Huang Shangti in the Taoist Trinity patterned after the Three Jewels of Buddhism. Present day Taoism is a conglomeration of animism, polytheism and magic.

### TARDIEU, ANDRÉ PIERRE GABRIEL AMÉDÉE (1876— ),

French politician and writer, was born in Paris Sept. 22 1876. Educated at the Ecole Normale Supérieure, he became *chef de cabinet* of Waldeck-Rousseau in 1899 and retained the post until 1902; between that year and 1914 he taught at the Ecole des Sciences Politiques and the Ecole Supérieure de la Guerre, and also acted as foreign news editor on *Le Temps*. From 1914–24, as deputy of the Chamber, he fulfilled the functions of French special commissioner in the United States (1917–8), of French plenipotentiary at the Peace Conference (1918–9), and Minister of the Liberated Regions (1919–20). As captain of Chasseurs between 1914 and 1916, he was wounded and three times mentioned in despatches. At the Peace Conference (1919) he was largely concerned with the proposals for the political and territorial clauses. He presided over the Committee of Five entrusted with the work of drafting the Allied Reply to the German Observations on the draft terms of the Peace Treaty. Tardieu also presided over the Alsace-Lorraine Committee, the Committee of the Saar and that of the execution of the Treaty.

Tardieu's political attitude was characterised by his inflexible attachment to the policy of Clemenceau, with whom he was associated in the closest collaboration for war and for peace. Three times in succession, between 1919 and 1924, he refused to enter the Government, in order to maintain his independent defence of this policy. As director of the *Echo National*, the daily paper founded by Clemenceau and himself, he waged a fierce war, in foreign affairs, against the successive revisions of the Treaty of Versailles; and in internal affairs, against the acts which paved the way for the victory of the *cortel des gauches*.

Tardieu was the author of the following historical works: *Questions Diplomatiques*. (1905); *France and the Alliances* (1908); *La conférence d'Algésiras* (1909); *Le Prince de Bulow* (1909); *Fürst v. Bulow* (1910); *La France et les alliances* (1910); *Le mystère d'Agadir* (1912); *Notes sur les Etats-Unis* (1917); *L'Amérique en armes* (1919); *La Paix* (1921); *Le Sleswig et la Paix* (1925).

**TARDIEU, RENÉ:** see BOYLESVE, RENÉ.

**TARIFFS** (see 26.422).—The history of commercial tariffs during the first quarter of the 20th century divides itself into three periods: the years prior to the World War, those covered by the conflict itself, and the years of readjustment that followed.

### I. THE PRE-WAR AND WAR PERIODS

The early years of the 20th century had found France, Germany and the United States definitely committed to protection, while in England the free-trade policy, though still dominant, was beginning to be seriously criticised. In the first three countries, the tariff schedules were already distinctly protectionist in character, the United States leading the way among these three in the application of high tariff rates for the encouragement of domestic manufactures; and France and Germany, in addition to indus-

trial protection, endeavouring to assist home agricultural production. The institution of imperial preference by Canada (1897) soon to be followed by similar measures on the part of other self-governing colonies and by Chamberlain's advocacy of reciprocity by England, unloosed a potent force toward protectionism. Not since the repeal of the Corn Laws had conditions appeared so favourable for a change in the free-trade policy of England.

**The German Tariff.**—Among the four countries above mentioned, the first after 1900 to effect a general amendment of its tariff was Germany. The agrarian interests, especially the large-scale producers of cereals, felt that their advantage had been sacrificed to that of the manufacturers and merchants in the commercial treaties negotiated by Count Caprivi in 1891–4.

The new tariff of 1902 provided for equal protection of manufactures and agricultural commodities, but on the whole support to the latter was the more conspicuous feature. Especially significant in this regard were the minimum tariff rates for certain agricultural products (*i.e.*, rates below which the Government might not make reductions in its negotiation of treaties), and the fact that the products thus particularly protected were rye, wheat, spelt, malting, barley and oats—the articles in which the large-scale producers were peculiarly interested. Industrial protection was enhanced in the law, however, and a much greater differentiation of rates was introduced. Objections had been raised to the whole system of "general" and "conventional" tariffs on the ground that concessions in the latter often affected a wide variety of articles, since the individual items in the tariffs often covered broad classes of goods. As many as 1,446 items were separately enumerated in this Act, whereas the older law had specified only 387 items. It was thus possible to limit the scope of concessions.

**The French Tariff.**—The increased height and the greater specialisation of the German tariff formed one basis for agitation in France in favour of a modification of the tariff law of that country. Further, it was held that for bargaining purposes the spread between the French minimum and the general or maximum tariff schedules—25 to 40% *ad valorem* in typical cases—should be increased. Finally, the French tariff had remained substantially unchanged since 1892, and in the interim new industries and new branches of old industries had arisen for which protection was believed advantageous.

In 1910 a new Act was passed which increased appreciably the protectionist character of the French tariff law. The rates of the maximum tariff were generally raised, new items were added to the law and numerous old minimum rates were increased or differentiated in a greater degree than before. Higher duties on special types of steel, on iron and steel products, especially tools and certain machinery, and on boots and shoes were typical and important alterations in the new Act. In marked contrast to the earlier German Act, the Act of 1910 was chiefly a vehicle for expanded protection to French manufacturers.

**The United States Tariff.**—The United States tariff of 1909, amending that established in 1897, failed appreciably to change the situation. It made certain reductions in duties, such as the rates on hides, wool tops and various iron and steel products; but, except in the case of hides, the reductions were in most cases more nominal than real. The lower rates were substantially as protective as the higher ones had been. Furthermore, the Act included various increases in duties, *e.g.*, on silk fabrics, certain forms of cutlery, hosiery and the like. The net result was to leave the general height of the tariff at much the same level as had previously ruled. The revision of 1909 in the end proved a political blunder as far as the Republican party in power was concerned. In the next presidential election (1912), the Democrats gained control of both the executive and legislative branches of the Government for the first time since 1892–4. Immediately the Democratic leaders began the revision of the tariff law. Most raw materials, including the most-favoured raw wool, were placed upon the free list; the complicated specific and compound schedules that had grown up in the Republican tariffs were largely scrapped; and the effective protection upon semi-manufactured and wholly manufactured articles was markedly de-

creased. The new Act had not been in operation a year when the World War broke out, and under the stress of that conflict the course of production and trade began to change rapidly and decisively. Not only was there no adequate test of the lower rates, but the conditions ultimately reached were so dissimilar to pre-War conditions that hopes of permanently lower tariff rates built upon the latter were rendered illusory.

### THE WAR PERIOD

With the outbreak of the World War came a break in the tariff experience of most important countries, especially those belligerent. Not only was the whole structure of conventional arrangements destroyed, but in the tariff legislation of the War years exigency replaced rational policy as the guiding motive. In part such legislation was dictated by desire for increased revenue. Examples are the increase in the Canadian tariff in 1915, the Australian advance in 1917 and the additions to pre-existing rates in England, France and Germany. Many alterations, however, in tariff arrangements, especially in Europe, were made for the control of commerce in the interest of the most effective prosecution of the War. In Germany, rates were lowered or abolished to facilitate the import of essential commodities. In France the executive was authorised (1916) to increase import duties upon any or all goods, and even to prohibit wholly the importation of articles in the interests of the country. Similarly, Great Britain in 1915 enacted the so-called McKenna duties: imposts of 33½% upon a number of luxury articles—pleasure cars, motor-cycles, watches and clocks, musical instruments and cinematograph films. These duties were partly devised for fiscal purposes, but in part also for economy in tonnage.

Ultimately, as the War dragged on and the strain upon national resources increased, import duties were found to be inadequate for the commercial control desired, and nations resorted to direct governmental supervision of the export and import of essential materials and foodstuffs. Licensing systems, supplementing governmental control of shipping and governmental bulk purchases, were adopted. The consumption of luxuries was thereby curtailed, cargo space in national and neutral ships conserved and the upward movement in the price of essential commodities somewhat restrained. Thus the declaration of peace found commerce trammelled by a multitude of restrictions and regulations.

### II. THE PERIOD OF RECONSTRUCTION

The direct and indirect effects of the World War, including those flowing from the War-time tariffs and War-sprung "controls," were of such magnitude that at the conclusion of peace a commercial and industrial situation largely novel confronted the nations of the world. The pre-War balance between industry and agriculture within nations had frequently been upset; old industries had been stimulated to expand and new industries had been born during the War's upheaval; while the prolonged rupture of pre-War commercial connections and the disturbed conditions of currency and exchange made it extremely difficult to gauge the strength of post-War basic forces.

Moreover, the War revealed many weaknesses in the organisation of industrial nations. England and Germany were hard pressed for food; most belligerents were forced to seek substitutes for essential raw materials; and at times even the lack of certain manufactured articles was annoying or really embarrassing. The last was especially true in cases where whole industries were throttled by scarcity of quantitatively minor elements: needles for knitting machines, dyestuffs for the textile manufacturers, gauges or chemical glassware for many sorts of work. National acquisition of such "key" industries seemed desirable.

Finally, the peace treaties brought into being a group of new nations, largely constituted out of portions of pre-existing nations. Upon separation, both the older nations and the newer areas—e. g., Austria-Hungary, Czechoslovakia and Yugoslavia—found themselves with unbalanced economic interests. The old markets for their surplus products were now on foreign soil. Furthermore, since many of the new nations were fired with an intense nationalistic sentiment, they were inclined to adopt measures to secure increased self-sufficiency. Similar ideas dominated the economic policy of countries whose power had increased, such as Australia, Italy and Turkey, or of countries which had gained more self-government, such as Ireland and India.

*Removal of Control.*—The first difficulty in the way of reconstruction—the licensing systems and other arbitrary methods of commercial control—was the easiest to surmount, although vari-

ous restrictions were maintained for several years. In England the change was rapid. The spring of 1919 found War-time restrictions still hampering British trade in 260 classes of goods, but Sept. of that same year saw the last of these restrictions wiped away. France moved in the same direction in the summer of 1919, but for a period in 1920 felt it necessary to reimpose control with respect to 175 articles. Germany and other countries, on the other hand, made progress more slowly, and the first seven years after the Armistice were marked by the frequent reintroduction of restrictions in various commodities. By 1926 interference with international trade by governmental systems of specific-commodity control had been largely eliminated.

The re-establishment of a new network of commercial treaties (q. v.), especially with a general use of the unconditional M.F.N. clause, proved a more arduous undertaking. For a time after the peace it seemed possible that no re-establishment along these lines would be effected. To the pre-War scepticism as to the general advantage of such engagements were added the uncertainties of economic conditions in the post-War period, some remnant of conviction among the Allied nations that the Central Powers should be treated for an indefinite time in a hostile manner, and the constraint placed upon independent action by Germany by the provisions of the Versailles Treaty. Yet, despite these handicaps, the project of renewing relations upon somewhat the same grounds as erstwhile had prevailed was initiated and slowly gained ground, first between Allied states, then between "enemy" states, between an Allied or "enemy" state and a neutral, or among the new nations created by the treaties of peace.

While the process of "de-control," and the re-establishment of conventional tariffs and treatment upon the basis of the M.F.N. clause, modified interference in international commerce, the characteristic feature of the reconstruction period remained the trend toward increased protectionism. The movement was broader and seemed more profound than anything which preceding decades knew.

*Great Britain.*—Colonial preference appeared for the first time in the British tariff system when in 1919 a reduction of a sixth was granted on dutiable goods (one-third off the McKenna rates above mentioned) which were the product or manufacture of British colonies; and in 1925 the preference on certain commodities, especially sugar, tobacco and dried fruits, was increased. In 1922 the Safeguarding of Industries Act was passed, levying duties of 33½% upon a number of "key" articles such as optical glass, scientific instruments, hosiery latch-needles, metallic tungsten and synthetic chemicals. Attempt at further advance along such lines was temporarily blocked when in 1923 the Conservatives appealed to the country and lost. However, after a short interval of Labour Government, during which repeal of the McKenna duties and a reduction of colonial preference were carried through, the Conservatives were again brought into power. The McKenna duties were re-established, additional Empire preferences approved and arrangements provided whereby the needs of individual industries (except the production of foodstuffs) could be given separate consideration with a view to tariff protection. (See SAFEGUARDING OF INDUSTRY.)

*The United States.*—Little was heard of tariff change in the United States for a year or two after the War. Then the conjunction of the severe crisis of 1920 with the return of the Republican party to control led to a renewal of tariff legislation. The crisis bore with somewhat exceptional severity upon the agricultural areas of the West, and for the first time in American tariff experience there appeared a broad group of agricultural interests asking for protection. At the same time industrial interests asked for a revision of the tariff, emphasising the increased competition of Germany and Japan, the need of protection for the industries initiated or expanded by the abnormal War-time conditions of commerce and manufacture, and the necessity of special defence against countries with depreciated paper-money currencies. First the farmers were partially satisfied by an "Emergency" tariff law (1921), which carried enhanced duties for a half-dozen important agricultural commodity classes. Then in the Tariff Act of 1922 protection was carried out more broadly than ever before—not unaffected by the circumstance of legislative "log-rolling." Agriculture secured duties higher than had ever been enacted; the "war babies," such as toys, tungsten and dyestuffs, secured specially high rates; and

manufacturing industries generally obtained something approaching the level of duties carried in the Payne-Aldrich Act of 1909, though with some exceptions. A few of these exceptions, e.g., cotton yarns and certain steel products, were reductions from the 1909 rates, although usually these reductions were more nominal than real; while the increases included some duties, such as those on cutlery and laces. The rate upon laces, 90%, was the highest simple *ad valorem* rate ever enacted for purely protective purposes.

*France.*—France established in 1919 a system of “co-efficients,” multiples by which the pre-War specific duties should be multiplied. In this way depreciation of the paper franc could be kept from weakening the protective wall. Then, two years later, a new maximum tariff was introduced, increasing the spread between minimum and maximum schedules. Whereas the difference had previously not been in excess of 100%, it became in some cases as much as 300%. Other countries followed the lead of France in the adoption of the co-efficient system: Belgium, Italy, Czechoslovakia, Poland and Turkey. *Germany* delayed the enactment of any general tariff law until 1925, when an Act was passed which placed the general level of the German tariff above that of the pre-War tariffs. Certain manufactures received increased support in the new duties, but especially notable was the restoration of the system of protective duties upon agricultural commodities approximately to the pre-War standard.

Industrial protection spread in less developed nations. Indeed, in one way or another, such protection coloured the post-War tariff enactments of Ireland, India, South Africa, New Zealand, Australia, Hungary, Lithuania, Czechoslovakia, Yugoslavia and Poland. In fact, scarcely a country of the world escaped the influence of the prevailing spirit.

The course of tariff history in the early years of post-War reconstruction manifested a trend in some respects more pronouncedly toward high and widespread protection than had been exhibited before the War. With the extension of the movement to the newer countries, and with the possibility of the downfall of free trade in its oldest home, the policy of Hamilton, List, Carey and Wagner seemed to carry everything before it.

(A. H. C.)

**TARKINGTON, NEWTON BOOTH** (1869– ), American author, was born in Indianapolis, Ind., July 29 1869. After studying at Phillips Academy, Exeter, Mass., he entered Purdue University, Lafayette, Ind., but later transferred to Princeton where he graduated in 1893. He was elected to the Indiana House of Representatives for the term 1902–3. His first story, *The Gentleman from Indiana*, was published in 1899, having appeared as a serial in *McClure's Magazine*. In 1900 his reputation was established by *Monsieur Beaucaire*, which he dramatised (with E. G. Sutherland) in 1901. In 1919 he was awarded the Pulitzer Prize for his novel, *The Magnificent Ambersons* (1918).

His other stories include *The Two Vanreuels* (1902); *Cherry* (1903); *The Conquest of Canaan* (1905); *Guest of Quesnay* (1908); *Beauty and the Jacobin: an Interlude of the French Revolution* (1912); *Penrod* (1914); *Penrod and Sam* (1916); *Ramsey Muholland* (1919); *Alice Adams* (1921); *Fascinating Stranger and Other Stories* (1923); *Women* (1925). His plays include *Cameo Kirby* (1907); *Your Humble Servant* (1908); *Mister Antonio* (1916); *The Country Cousin* (1917), with Julian Street; *The Gibson Upright and Up From Nowhere* (1919), both with Harry Leon Wilson; *Clarence* (1919); *Seventeen* (1925).

**TASMANIA** (see 26.438), a state of the Australian Commonwealth. The island of Tasmania, the smallest of the Australian States, has an area of 26,215 sq. miles. Its population in 1925 was 211,906, an increase of 20,695 since 1911. Hobart (population 56,507) is the capital and chief port. Launceston (population 28,000) is the principal town in the north. Overseas mail steamers do not call at Tasmania, but there are regular shipping services with Melbourne and Sydney. The states

returns six Senators and five members of the House of Representatives to the Federal Parliament. The Legislative Council has 18 members and the House of Assembly 30. Since the War political power has fluctuated between the Nationalists and Country party on the one hand and Labour on the other. The state owns and controls a hydroelectric undertaking, a shipping service and an insurance office.

*Production and Industry.*—Tasmania reproduces many of the natural features of England, and its climatic conditions closely resemble those of western Europe. Drought is unknown, and the fruits, flowers and vegetables of the temperate zone are successfully grown. In 1924, 34,076 ac. were under cultivation as orchards and fruit gardens, of which 25,681 ac. were devoted to the production of apples. Oats, beans, peas and potatoes are other crops and hops are grown.

Minerals to the value of £1,154,397 were produced in Tasmania in 1923. In that year copper was the principal product, with tin, lead, limestone, flux and silver following in the order named. Tasmania is the largest producer of “free” osmiridium in the world: in 1920, 2,009 oz., valued at £77,114, were produced. The development of secondary industries during the post-War period was due, to a large extent, to the utilisation of the Great Lake waters to develop electric power. In 1924 the state hydroelectric department had available from this scheme 63,000 H.P., capable of development to 500,000 H.P. Foremost among the industries is that of the Electrolytic Zinc Co. of Australasia. Messrs. Cadbury, Fry and Pascall established a joint factory at Hobart in 1922, and several woollen manufacturers from Great Britain have established factories at Launceston (see AUSTRALIA).

**TATA, SIR DORABJI JAMSETJI** (1859– ), Indian capitalist, was born at Bombay on Aug. 27 1859, being the elder son of the famous Parsee industrial pioneer, Jamsetji Nasarwanji Tata (see 26.448). Upon leaving Cambridge, he entered his father's business and pursued his father's great conceptions until they culminated in striking advances in Indian industrial development and also in the establishment in 1905, by means of generous endowment, of the Indian institute of scientific research at Bangalore. He was actively assisted by his brother Sir Ratan Tata (1871–1918) and after many disappointments he secured by the end of 1911 the establishment of iron and steel manufactures on a large scale with Indian capital and under Indian control. From the jungle of a remote Bengal district there sprung the town of Jamshedpur, so named (like the adjacent Tatanagar) after the originator of the project. A population of over 80,000 is there engaged in steel manufacture and many subsidiary industries.

Sir Dorabji, who was knighted at the beginning of 1910, showed pertinacity in carrying to realisation a succession of schemes for harnessing the heavy monsoon rainfall of the Western Ghats to provide the hydroelectric energy which has vastly increased the productive capacity and transformed the industrial conditions of the city and neighbourhood of Bombay. Altogether the Tata concerns support 250,000 wage earners and their dependents, and represent a capital commitment (almost entirely Indian), estimated at £50,000,000. Suffering from the reactions of the speculative boom of the post-Armistice period, and from severe external competition, the parent steel company sought and was the first Indian industrial concern to receive, by legislative enactment in 1924, the discriminating protection recommended as a suitable policy for India by the Fiscal Commission of 1921–2. Sir Dorabji's cousin, Sharpuji Saklatvala, was the first Communist to be elected to the British House of Commons, being returned for Battersea in 1922 and again in 1924.

**TAUSSIG, FRANK WILLIAM** (1859– ), American economist (see 26.456), was during 1917–9 chairman of the U.S. Tariff Commission. In March 1919, he was called to Paris to advise in the adjustment of commercial treaties, and in Nov., attended the second industrial conference in Washington for promoting peace between capital and labour. He was a strong supporter of the Covenant of the League of Nations.

Taussig wrote, *Principles of Economics* (1911; 3rd ed., 1921); *Some Phases of the Tariff Question* (1915); *Investors and Money-Makers* (1915); and *Free Trade, the Tariff, and Reciprocity* (1919).

**TAXATION** (*see* 26.458).—In a post-War discussion of the fundamental principles of taxation Mr. Andrew W. Mellon, Secretary of the Treasury of the United States, said that a sound tax policy should (1) produce sufficient revenue for the Government; (2) lessen as far as possible the burden on those least able to bear it; and (3) remove influences which retard the development of business and industry. In substance that programme is merely another method of stating the canons of taxation laid down by Adam Smith—equality or ability, certainty, convenience and economy. One authority has suggested that these in turn resolve themselves into one grand principle of economy. In this connection, however, economy is a highly technical term, and not the mere reduction of expenditure which is the misleading feature of much of our popular debate.

#### VIEWS OF TAX AUTHORITIES

Mr. Mellon also argued that a tax system should be designed not for one or two years, or from the standpoint of any given class; it should apply to a long period, and with a view to its effect on the prosperity of the country as a whole. While his appeal was addressed mainly to the American public grappling with what he considered the high income-tax following the World War, and was certainly influenced by the unmistakable tendency in the United States to make ever larger investment in the remarkable volume of tax-exempt securities, the message was regarded as one equally appropriate in Great Britain, certainly in the conditions which had followed the European conflict. In any review of British taxation in the period since 1910 the practical revolution in finance after 1914 must be the dominating feature; but however great the spectacular changes fundamental principles remain. Mr. Mellon's contribution was necessarily general. It was perhaps too strongly an appeal from the bosom of large-scale business, with the almost exclusive suggestion that taxation had only to be reduced to make the desert blossom as the rose.

In his Newmarch lectures for 1919 Sir Josiah Stamp went very much nearer to realities. Concentrating on the four points that taxation is to-day a dominating feature of daily life, that there is much greater complexity in modern economic conditions, that there is now a growing field of State activity, and that above all there is the financial legacy of the World War, he proceeded to a three-fold analysis from the standpoint of the taxpayer, of the Govt. acting for the community in its State organisation, and of the community as a producing or economic society. Such a method would enable us to understand the principles and the trend of taxation at any time. But it is specially valuable in an effort to understand the period 1910-26. For that period is in many respects a vivid illustration of the truth of his statement that most taxes in practice represent the best practical compromise in the three standpoints that can be arranged in the particular circumstances of the time.

#### THE PRINCIPLE OF ABILITY TO PAY

The largely increased burden of taxation in Great Britain that followed the Boer War and to a greater extent the European conflict suggested fresh analysis of the principle of ability to pay. It has not in practice done more than modify to a small extent the methods previously in force. The benefit principle (or the payment of taxation in proportion to benefit derived from public service of one kind and another) appealed to many who were influenced by new doctrines affecting the recognition of personal and public sacrifice in post-War conditions. Natural but impracticable was Sir Josiah Stamp's summary of the principle; and events confirm the impression that even in times of great financial upheaval the principle must be regarded from the standpoint of what is practicable. Recourse to the principle of ability to pay is inevitable; but ability must be measured by something more than the mere possession of monetary resources. That test should be supplemented by reference to the consumption of certain commodities which, if not among the strict necessities of life, have been regarded by Marshall and other leading economists as among the conventional necessities or minor comforts.

Broadly speaking the period 1910-26 has witnessed a desire to

relieve necessities, and to-day the proportion of revenue raised from indirect as compared with direct taxation is 36.64, as against the pre-War tendency to raise revenue as far as possible on the basis of 50-50. No particular reason or merit attached to that apparent equality. Indirect taxation is not so strictly related to ability to pay; but, assuming for the moment inability to pass on to consumers more than a limited part of direct taxation, indirect taxes are defended on the ground that they reach the masses for a reasonable contribution which can be collected by direct taxation only with very great difficulty, who under a much more comprehensive scheme of income tax than anyone is prepared to propose would in any event have been liable for little or no direct taxation, and who prefer to pay in the price of the commodity in the belief (however unsound economically) that the indirect impost is not so heavy a burden. Advocates of the "free breakfast table" are still alive, and reasonably active. They cannot, however, ignore the appalling load the State has to carry, and their effort now is not so much to get rid of indirect taxation altogether as to see that it falls on commodities which can always be regarded as quasi-luxurious or definitely luxurious in character.

**Personal Taxation.**—In the same period there has also been definite consolidation of the movement away from real or specific taxes (that is, on property or annual valuation) to personal taxes, described by most writers as the transition from objective to subjective. The objective is still powerful in local rating, by no means a negligible aspect of present-day taxation. In the country as a whole the movement to "sensitive subjective taxation" is undeniable. These principles were abundantly illustrated in the proceedings before the Royal Commission on the Income Tax in 1919, in its report of the following year, and in many of the parliamentary discussions on the application of tax-concessions which it recommended. Early approaches to personal taxation broke down. Proper taxation on income is impossible in a community not reasonably advanced in people and government. The evidence tendered to the Royal Commission, together with much of the recent analysis of British economic organisation, shows that the foundations for personal or subjective taxation are now broad and secure. The administrative and other machinery is ample.

Although in many respects Great Britain lags behind the United States and certain other countries, her statistical measurement of social and industrial conditions has made progress. In industry the elimination of small-scale production and inefficient bookkeeping, and the appearance of public company, combine and trust—all involving some progress in the publicity which Mr. Sidney Webb among others has urged as desirable—have made it easier to ascertain the precise allocation to individuals. And the movement tends to be further consolidated by administrative practice like deduction of tax at the source, that is, before the dividend reaches the taxpayer at all, giving the State on the one hand its revenue at an earlier moment, and with greater security, and on the other awakening the interest of the taxpayer in the general system at all events in claiming the refund of something less than deduction at the maximum scale, which is for him the effective rate.

But in spite of all the developments of recent years there is still no country in the world in which the system of taxation is strictly true to first or fundamental principles. In Great Britain, as elsewhere, there are many of the accidents of commercial and political conditions. There are innumerable curious historical survivals. One by one, like inhabited house duty, they tend to disappear. All that can be said with firm accuracy is that, everything considered, the tendency since 1910 has been towards a certain simplification in the midst of a quite definite hardening in favour of personal or subjective tax.

**Methods of Assessment.**—Turning now to the strictly individual standpoint of the British taxpayer, the facts are plain and even simple. The method of regarding income by the year remains subject to the modification of quarterly assessment for weekly wage-earners. That is one concession to the shorter period. There is fresh insistence on the rule that tax should follow closely the period of computation. The Royal Commission on the Income

Tax recognised that deduction at the source, covering a large part of the aggregate income yearly brought under review, formed a great safeguard for the revenue; but it also recommended that in the wide sphere of business profits, commonly known as schedule D, the three years' average should be abolished. Undeniably the year of assessment is the ideal basis; as a matter of practical politics the commission proposed the preceding year, and that recommendation was embodied in the Finance Bill of 1926. No real inroad has been made on the principle of annual value in this country. America emphasises capital value; only to a very limited extent is that found in the British system. Nor is there definite tendency to bring within the scope of income tax the profits of occasional transactions in stocks, shares or other classes of property. Only when such transactions become so regular as to amount to settled business do they take their place in the taxable material of the time.

For large numbers of individual taxpayers there has been more controversy regarding the suggestion that the dividend resulting from co-operative trading should be taxed. That the gain derived from mutual trading should be regarded as a profit in the ordinary commercial sense has been hotly disputed. Most Governments have come to the conclusion that, whatever the economic merits of the dispute, any attempt so to tax the dividends of nearly 5,000,000 of the community is not worth the candle, mainly because the great majority would be entitled to refund as not coming within the present range of income-tax after family and other allowances have been conceded, and partly because the co-operative movement has but to lower the prices of its commodities to eliminate any distribution at all in dividend form and therefore to take away the taxable material. Comparisons of municipal trading with ordinary private trading profits have been erroneous; most of them have suggested that income tax enters into costs, a contention which is still generally regarded as unsound.

Progressive taxation on income (that is, increasing in rate as the income increases) is now universal; practice in the period under review has been all in the direction of entrenching it more firmly than ever in the British system. McCulloch took the odd view that taxpayers should be left in the same relative position in which they had been found! Not even the strongest opponent of direct taxation would to-day offer that argument on a public platform. Most of the economists have reminded us that progression rests on the diminishing utility of money or wealth to its possessor; and to that basic principle there is no real challenge in the argument that wants satisfied by early increments to income are of more importance than wants satisfied by late increments, an argument advanced apparently by way of modification. But for present-day purposes the practical justification of progression is usually its place in the campaign for social improvement. Professor Marshall spoke of the State using its powers for prompting such economic and social adjustments as will make for the well-being of the people at large. Much has been made of the doctrine of least aggregate sacrifice.

Perhaps the only check has been the economic effect of excessive taxation on capital accretion, and the danger that that may in turn react upon the people in their employment and industrial progress. At certain levels taxation may amount to confiscation; and it is sometimes contended that the doubts entertained by some of the opponents of graduation last century have been justified. The reply is probably complete. There is first the general desire to reduce taxation; secondly, a mass of concessions covering business and family life; and thirdly, especially since 1915, growing recognition of the fact that at best taxation is only limited and sometimes even a dangerous instrument for the readjustment of social conditions. On the last point the emphasis now laid on all manner of schemes for the alteration of ownership, in the sense of diffusion, cannot escape observation. And it is also recognised that there is an everlasting conflict of principle in the measurement of taxable ability by income and the economic and social importance of not discouraging (under any system of industrial ownership) the accumulation of capital.

Reference has been made to the taxation of special ability to

pay. Since 1910 this problem has been represented in efforts to impose duties on the increment value of land. The common argument is that that increment, especially in large centres, is not due to the work or sacrifice of the owner, but almost entirely to the enterprise and growth of the surrounding community; that in effect the value is publicly created, and should be in the main publicly appropriated; and that the case for such appropriation is all the stronger when such steps will promote or hasten schemes of civic betterment and force land into remunerative use. More cautious minds have tried to plead that the increment may be in many cases the "accumulation of compound interest on a site that waited a long time before ripening into full salability." Here the analysis need not be pressed, for even if such an element is admitted it is true that there is much increment which is clearly the property of the community. The period in question witnessed a complicated attempt in Great Britain to secure a considerable proportion of this increment for the people, but the attempt, now abandoned, perhaps owed its lack of success mainly to failure to apply the system effectively to the remarkable complexity of the laws affecting real property.

During the World War that form of taxation was in difficulty and there was much keener interest in the discussion of corporation profits tax, taxation of war wealth, excess profits duty and capital levy, all of which represented efforts to secure for the community (partly as an immediate contribution to revenue and in the case of the capital levy for the specific reduction of war debt) some portion of the windfall or special gain which war conditions had brought to certain sections of the people. To a Select Committee of the House of Commons the Inland Revenue authorities stated that a tax on war wealth was administratively practicable. The Labour movement in particular pleaded for a levy on capital. Both proposals were rejected by successive Govts.; but excess profits duty and corporation profits tax were applied.

The former tax took a basic or standard year in the profits of the business brought within the duty; above that standard percentages of the war profits were taken in taxation; but in Finance Acts following the War firms were allowed the set-off of subsequent loss, with the result that the net yield to the Exchequer must in the long run be comparatively small. Corporation profits tax was a tax on the undistributed profits of certain companies. It has been abolished. It would, however, be wrong to suggest that these facts are due entirely to the difficulty of introducing any form of taxation on windfall or special ability to pay in Great Britain. They were powerful in doctrine and revenue during the War; but like many other special devices they could not survive industrial depression. In other words, British economic conditions were not favourable to their obtaining a permanent place in our fiscal system. Meanwhile there were constant references to the taxation of special ability abroad; notable in the public imposts on cash prizes in Australian lotteries; and eventually, in 1926, the Chancellor of the Exchequer announced a 5% duty on betting turnover in Great Britain, not, however, so much on the basis of windfall or special ability to pay as on the suggestion that betting was a luxury which anyone could give up at will and was, in the special circumstances of the time, appropriate taxable material.

#### INDIRECT TAXATION

Side by side with the tendencies described there has been unwearying analysis of indirect taxation. In taxation on expenditure it is recognised that no duty on commodities can be properly progressive; that if articles in common use are taken, as they must be to give security to the revenue, the system is generally regressive; and that countries which have extensive tariffs are generally rich in illustration of the manner in which the burden varies inversely to ability to pay. But, as has been already suggested, indirect taxation cannot in debate stand by itself. If that were possible there would be no economic defence. For all practical purposes to-day and this has been specially emphasised in the remarkable revenue conditions since 1910—it must be regarded as a preferably minor part of a wider general scheme of taxation,

always to be carefully scrutinised, and calculated to reach an area which cannot be effectively tapped by direct taxation. This has suggested the selection of a wide list of commodity taxes which attack the non-functional element in spending (or the element not strictly necessary to the discharge of duty by the individual affected) in a manner which income tax could not attempt. But from the sphere of income tax, where regard is had to the family as a unit for fiscal purposes, there is some encouragement of this doctrine in the indirect area.

A tax on turnover (*see* **TURNOVER TAX**) is large-scale application of taxation to expenditure, but while it is taken as the basis for the British betting duty proposals it is not elsewhere practical politics. Few taxes are so thoroughly unfair in their incidence, and few lend themselves so readily to evasion, so that the fundamental arguments against the device are at all times powerful. Broadly speaking, therefore, in indirect taxation there had been a movement away from the 50% allocation of burden in raising total revenue in Great Britain; concessions have been given on the strict necessities of life; indirect taxation has been centred on minor comforts and on luxuries; and under the Govt. which took office in 1924 there has been substantial recourse to the non-functional surplus in spending.

Concluding this summary from the standpoint of the individual it may be said that there has been little or no taxation of capital as such. In certain wasting assets, such as leaseholds, there is in practice some mixture of taxation of income and of capital; but this tendency, limited as it is, should be corrected when the British Parliament adopts the programme for the treatment of wasting assets which was recommended by the Royal Commission on the Income Tax in 1919.

#### SOME GENERAL PRINCIPLES

Since in Great Britain the movement towards personal or subjective taxation is pronounced, the review must be devoted very largely to that aspect. The standpoint of the state and of the community is, however, of importance. Sir Josiah Stamp has summarised the questions which confront the community in asking whether the proposed tax is economical, workable, specially open to evasion or dishonesty, likely to dry up the source and prove abortive to the revenue, raise political difficulties and create unrest or raise international problems and provoke conflict with other taxing jurisdictions.

Since 1911, but more especially in the international issues raised after the World War in interminable debt adjustment, these questions have occupied a large place in domestic fiscal legislation. Domestic imposts and the problems raised by fiscal relationships with other countries are, of course, very closely related. The whole range of discussion is in fact raised in the simplest issues. Of late the community has had to consider carefully the incidence of taxation. Will a tax of certain weight on tea diminish consumption and encourage the use of substitutes? Will a turnover tax play into the hands of larger firms which control the various stages of production and distribution, to the disadvantage of their smaller competitors? Is there a case to-day for the special taxation of certain industries? Or will such taxation in practice cause a fall in the value of their stocks such as will amount to capitalisation of the tax? The consideration of such questions has helped Great Britain to preserve reasonable balance of direct and indirect taxation, with a tendency to reduce the latter; to avoid the dangers of turnover taxation; and, in the main, to avoid differential taxation. For it is clear that the last is in reality a form of confiscation for present owners, just as differential exemption or privilege tends to be a bonus to present owners.

But there is still much differential privilege, as in the concessions to agriculture and the method of assessing the profits of farmers, now on the basis of the annual valuation of their holdings. Recognising the danger of this underlying doctrine the Royal Commission on the Income Tax unanimously recommended that farmers should be brought under schedule D for taxation on actual profit like other trading classes of the community. So far that recommendation has not been adopted. Still, it is a definite statement of sound economic practice in the field of differen-

tial treatment, even if it must be admitted that the Finance Acts of recent years in Great Britain contain many minor concessions which, taken together, come dangerously near to substantial attack on the principle.

Certain old taxes like some of the land taxes are, so to speak, no taxes, since they have been capitalised. Of the economic effect of the death duties, which are admittedly a tax on capital, the reasoned conclusion appears to be that at worst "a new capital form has been prevented from coming into being," that much depends on what the Govt. does with the money, that if the use is remunerative the net effect on national capital is nil, and that the real problem is not so much any immediate adverse effect of the death duties as the dynamic aspect (from the standpoint of accumulation) over a series of years. Practice since 1910 has again entrenched such duties; economically the argument that they should be specifically allocated for debt reduction is both creditable and sound, since they are of the nature of capital levy; but on the other hand the British Exchequer has generally supported the growing objection to anything of the nature of an assigned revenue, an attitude strikingly illustrated in the proposals affecting the Road Fund in the Finance Bill of 1926.

The ulterior objects of taxation vary; most of the critics regard them as allowable, subject to the condition that they are always secondary. In so far as they attempt the redistribution of wealth, for example, they should be limited by the doctrine of fair progression. In so far as import duties—a growing phase of the British fiscal system since 1910—are imposed the argument is that they should not reduce the aggregate volume of trade; but in that connection the ulterior object is much more debatable. In the period under review there has been no substantial modification of Britain's system of free imports. The War and post-War programme has been first of all an effort to safeguard, by uniform duty, certain industries believed to be vital in time of emergency; and secondly, again as a rule, by uniform duty of 33 $\frac{1}{3}$ %, to give a form of protection to home producers against imported commodities enjoying the export advantage of depreciated exchange, produced under conditions abroad calculated to give unfair advantage to the country of origin, or reaching Great Britain in such quantities as to amount to "dumping" in the sense of being retained within these islands in competitive sale with British goods.

Finally, post-War financial conditions have revived discussion of many of the intricacies of the limits of taxable capacity. It is one of the abiding problems of taxation, but the large budgets of recent times, the difficulties of the repayment of Govt. debt, and the question as to how far Germany could be made to pay for the War (including the searching analysis which preceded the introduction of the Dawes scheme) have led to much wider discussion. It has proved remarkably hard to arrive at the relative capacity of different countries to bear taxation, but the ultimate test has been what is left to the inhabitants together with what they derive from outside their own borders. The manner in which wealth is distributed is a material factor, and there is always the duty of observing a close relationship in consumption and production levels. In Great Britain much has been made in debate of "pre-War standards," a basis which is often irrelevant and misleading in the changed conditions which confront national finance. But broadly there is now much better recognition of the fact that the limit of taxable capacity is not absolute or fixed. The essential considerations are that much depends on the uses to which the revenue is put; great importance must be attached to the spirit of the people who are bearing the taxation, and the manner in which they regard it; the way in which the taxation is raised may of itself largely influence the position; and effective use can be made of the truth that great advantage is to be derived from the employment of resources for the reduction of debt, especially external debt.

These principles underlay the determination of the British Govt. in 1922 to fund, under arrangement with the United States of America, what was by far the largest part of their post-War external indebtedness. To a country depending largely on overseas trade, and therefore committed to a long view of the exchange problem, such a course was inevitable. But it had to be supported

by drastic taxation at home, and by the rigorous balancing of budgets, together with reasonable provision for debt redemption, all of which were linked up with the preparation for return to the gold standard and the re-establishment of London as the financial centre of the world. To that end the system of taxation, especially since the conclusion of the World War, has made remarkable contribution. **TAYLOR, FREDERICK WINSLOW** (1856–1915) American engineer, was born March 20 1856, at Germantown, Pennsylvania. Prevented by impaired eyesight from entering Harvard University, for which he had prepared, he in 1874 began an apprenticeship as pattern-maker and machinist in a small Philadelphia shop. In 1878 he entered the employ of the Midvale Steel Co. as yard labourer, but was promoted rapidly to time-keeper, gang boss, assistant foreman, foreman, assistant engineer and chief engineer (informally in 1884, formally in 1887). In the meantime, his eyesight having been restored, he earned by night study the M.E. degree from Stevens Institute. In 1898 he was employed by the Bethlehem Steel Co., and after 1901 he devoted his entire time to forwarding by educational means the principles of scientific management (see article). As early as 1880 or 1881, while gang boss, controversy with workers had led him to realise the necessity of accurate measurement of what constituted a day's work on any operation. This in turn led to a series of careful experiments resulting in important achievements in two fields; in mechanical engineering, the discovery with Maunsel White of a new method of tempering tool steel permitting metal-cutting operations at high speed (1898); and in the field of management, perfection of that system of shop management which came later to be known as scientific management. He died March 21 1915, at Philadelphia.

Taylor's publications include *Notes on Belting* (1893); *The Adjustment of Wages to Efficiency; A Piece Rate System* (1896); *On the Art of Cutting Metals* (1906); *Shop Management* (1911); *The Principles of Scientific Management* (1911); and with S. E. Thompson, *A Treatise on Concrete, Plain and Reinforced*, 3rd ed. (1916). See F. B. Copley, *Frederick W. Taylor*, 2 vol. (1923).

**TEA** (see 26.476).—In 1925 the International Institute of Agriculture at Rome estimated the world production of tea at between 1,750 and 2,000 million pounds. The area under tea in India was in 1924 computed at 716,300 ac. of which 83% was in Assam, Darjeeling and Jalpaiguri. Of the 375,000,000 lb. produced in 1924, Northern India accounted for 329,000,000 lb. and Southern India for 46,000,000 pounds. Four hundred and twelve thousand ac. produced in 1925 209,500,000 lb. of tea. In the same year the production in Java amounted to 94,500,000 lb. from about 220,000 ac. and in Sumatra the produce of 30,000 ac. totalled 17,000,000 pounds. As regards China which, unlike India and Ceylon, is a country of small producers, statistics of production are necessarily vague. The total production is estimated at about 1,000,000,000 lb. annually, less than 100,000,000 lb. of which are exported.

In Japan 115,000 ac. are under tea, producing some 75,000,000 lb. annually, almost all being unfermented green tea, two-thirds of which is consumed in the country, the remainder being sent to the United States and to Canada. The island of Formosa has about 90,000 ac. planted, and produces from 30,000,000 to 35,000,000 lb. each year, most of it going to the United States. In Africa, the Natal tea industry is declining; but in Nyasaland it is increasing, 5,000 ac. being planted on the slopes of the Mlanje Mountain: about 1,000,000 lb. were exported in 1925. In Uganda and Kenya experimental planting shows promise. A small quantity of Annamese tea has appeared on the London

market. In Brazil attempts are being made to grow tea from Assam seed, and in Transcaucasia tea-growing is becoming an important industry.

*Increase of World-Consumption.*—The world-wide consumption of tea is increasing. The United Kingdom is the largest consumer—during 1925 duty was paid on over 400,000,000 lb. for home consumption, equal to nearly nine lb. per head of the population. Canada, Australia, and New Zealand show an even larger consumption per head. Other countries are slowly acquiring the taste for tea, and energetic efforts are being made to develop the markets both in the United States and in France. In March 1924 the Indian planters voted £20,000 for promoting the sale of their tea in France, and £40,000 for similar propaganda in the United States. It is expected that prohibition in the latter country will stimulate the demand for tea.

Before the War Russia was a large consumer; her imports of other than China tea during the period 1909–13 averaging over 157,000,000 lb. per annum, of which 50% came from India, 25% from Ceylon, and 25% from Java. During 1925 direct shipments and re-exports to European Russia totalled only 16,250,000 lb., of which about 45% came from India, 35% from Ceylon and 20% from Java. It is known that Russia is taking large quantities from China overland. The Soviet Govt. by her trading system is securing large supplies, China being the main source. The method of financing the Russian buying is not easily traceable on the market. The official buying organisation puts its business through brokers on a cash basis to some extent, but needing credit it also buys through groups of financiers in various countries who, in turn, operate through brokers or dealers.

*Distribution of Exports and Imports.*—The exports from producing countries in 1925 were as follows:—

|                             | lb.         |
|-----------------------------|-------------|
| Northern India . . . . .    | 304,544,265 |
| Southern India . . . . .    | 43,948,848  |
| Ceylon . . . . .            | 205,493,536 |
| Java . . . . .              | 94,037,988  |
| Sumatra . . . . .           | 16,654,053  |
| Nyasaland . . . . .         | 1,114,633   |
| China (estimated) . . . . . | 86,000,000  |
| Japan . . . . .             | 27,759,600  |
| Formosa . . . . .           | 20,842,800  |
| Total . . . . .             | 800,395,723 |

Imports into the principal consuming countries during 1925 were as follows:—

|                                    | lb.         |
|------------------------------------|-------------|
| Great Britain . . . . .            | 491,000,000 |
| Irish Free State . . . . .         | 23,305,000  |
| United States of America . . . . . | 100,962,000 |
| Australia . . . . .                | 48,833,000  |
| Canada . . . . .                   | 35,785,000  |
| New Zealand . . . . .              | 18,764,000  |
| Morocco . . . . .                  | 10,199,000  |
| S. Africa . . . . .                | 9,387,000   |
| Germany . . . . .                  | 8,934,000   |
| Egypt . . . . .                    | 8,229,000   |
| Chile . . . . .                    | 4,460,000   |
| Argentina . . . . .                | 4,370,000   |
| France . . . . .                   | 3,654,000   |
| Poland . . . . .                   | 3,194,000   |
| Algiers . . . . .                  | 1,677,000   |
| Denmark . . . . .                  | 1,436,000   |

*The British Market.*—During the World War a Board of Control was instituted under which distributing firms balloted monthly for the tea available, this being divided according to quality into three grades. The producer was granted a fair price as shipments from India and Ceylon were arranged by the Government, and imports from China and Java were prohibited. The retail distributor was rationed as to the quantity he might draw and it was required that the retail price to the public should not exceed 2s. 8d. per lb., even though the duty was, in Sept. 1915 increased to 1s. per lb. and the stocks in the United Kingdom reduced by Dec. 1917 to 37,500,000 pounds. It was also required that tea should be sold retail by net weight—a requirement still in force. After the conclusion of peace, decontrol gradually took place. In 1919 imports from all sources were again permitted and the free marketing of tea resumed. The trade was, however, confronted with some difficulties, the chief being a glut of tea on the market due to a record supply being available and the absence of a demand from consuming countries. Free shipping and supplies available from all places, aided by large re-exports from the United States, resulted in the import of over 500,000,000 lb. during 1919. Stocks grew to over 210,000,000 lb. and the expectation that these could be liquidated by the demand

from other consuming countries than the United States proved illusory. These factors influenced prices and common tea was in 1920 sold down to 5½d. per lb., a price below producer's costs. Subsequently prices gradually improved, until in 1924 a new high record for common tea was created when the price touched 1s. 8½d. per pound. The average prices of British-grown teas on the London market were as follows:—

|                   | 1924        | 1925        |
|-------------------|-------------|-------------|
| Assam             | 1s. 7-84d.  | 1s. 9-04d.  |
| Darjeeling        | 1s. 9-97d.  | 1s. 9-63d.  |
| Duars             | 1s. 3-77d.  | 1s. 7-41d.  |
| Cachar and Sylhet | 1s. 2-15d.  | 1s. 6-29d.  |
| Ceylon            | 1s. 11-85d. | 1s. 10-72d. |
| S. India          | 1s. 10-32d. | 1s. 9-03d.  |

To these prices must be added the import duty which, early in 1926, was 3½d. per lb. for Empire-grown sorts and 4d. per lb. for foreign-grown. (C. L. T. B.)

**TEACHING.**—The period 1910-25 was one of unexampled educational activity and development, not confined to the Western nations but almost world-wide in range. While most of the ideas now taking shape in the national systems were active on a small scale before 1914, the moral shock of the World War was undoubtedly the cause of their present influence. This is seen particularly in Germany, the land where the older educational tradition was fullest developed and most firmly established, which has, since the revolution, been the theatre of a remarkable educational ferment productive already of far-reaching changes. Education in Russia has undergone a still more dramatic upheaval; but the transformation of the schools under Soviet rule though known to be very great, has as yet been insufficiently observed by competent Western critics. In the countries where educational methods were less well defined and less rigid, and where there has been less political disturbance, the changes, though not so conspicuous, are still highly important both in actuality and in potentiality for the future; and Belgium, England, France, Italy and the United States have all made significant contributions to a truly international movement.

*The Pre-War Movement.*—Before the War zeal for national efficiency was, on the whole, the dominating motive in education. Under modern conditions economic prosperity was perceived to depend increasingly upon the spread of knowledge among the masses of a people, and upon the production of men, well informed, trained and disciplined, capable of exercising leadership in the several branches of its affairs; and the trend of political changes conspired with industrial and commercial developments to make sound education a national necessity. Largely under the stimulus of this motive, elementary education became, in all the progressive countries, at once more liberal in scope and more practical in outlook; and countries like England, which had done comparatively little for their secondary schools, began to foster them sedulously (see *SECONDARY SCHOOLS*). Everywhere attempts were made to bring school teaching into closer touch with the facts and needs of ordinary life and with the national interests.

Many important advances in teaching and teaching methods thus came about: for instance, a notable extension of practical teaching in science, especially in England, a treatment of geography which made it a rational discipline helping the student to understand essential features of the modern world, the "direct method" of teaching foreign languages (*q.v.*) which sought to make the study of a tongue a key to the life and mind of the people who speak it, and the development, particularly in America, of instruction in manual and domestic arts. And side by side with these advances in the teaching of the elementary and secondary schools there was a corresponding growth of technical education (*q.v.*), which aimed still more directly at national efficiency, and led to much useful experimenting in the methods of teaching and training young people for industrial, commercial and domestic occupations.

*Post-War Changes.*—Since 1918 the pre-War movement has been resumed, but other ideas than national efficiency are conspicuous, and seem likely to produce profounder changes in school organisation and teaching. These derive their force

ultimately from the democratic faith that the purpose of education should be to secure for every person the fullest life of which he is capable, and their operation has been directed by the wider and deeper psychological knowledge that has become available. In brief, education tends increasingly to start from Rousseau's position that youth is not a preparation for life but a part of life, and seeks to make that part as rich as possible in itself in the belief that this is to make it as fruitful as possible in subsequent values. And with this attitude is combined the psychological doctrine that life is essentially spontaneity or "self-activity," which is always motivated from within though its course is necessarily determined largely by environment and external guidance.

*Montessori and Other Systems.*—Dr. Maria Montessori's methods in the education of young children offer a simple model of the way in which these ideas work out. (See *MONTESSEORI SYSTEM*.) The essence of her scheme is to provide for a group of children a series of carefully devised occupations and then to leave the individuals of the group to educate themselves by self-chosen activity under the eye of a "directress," whose function is to watch carefully the progress of her charges and to interfere with them as little as possible. The occupations are believed all to contribute to the child's mental and moral development, and are designed so that he can observe his own progress and success in them; they range from simple exercises for training senses and movements up to self-initiation into the arts of reading, writing and reckoning.

While Montessori's system as a whole has not been very largely adopted, her cardinal idea, under the name of "individual work," has spread widely in infants' schools in England and elsewhere, modifying or replacing the tradition of the Froebel kindergarten. It has also helped to inspire numerous attempts to break away from the old-fashioned routine of class-instruction in the education of older scholars, and to give, in both elementary and secondary schools, a larger place to individual and self-directed study and practical activity. Some of the more systematic of these attempts (*e.g.*, the "Dalton Plan," the "Winnetka Plan," the "Howard Plan") have been studied more widely than they have been imitated, but the general influence of the ideas they incorporate is unmistakable, and in spite of some short-lived extravagances has been salutary and vivifying.

*The Influence of Dewey.*—Long before Dr. Montessori gave fresh vigour to the notion of individual self-education, Professor John Dewey, then of Chicago, had worked out his doctrine of education not merely for but through activities of social value. This doctrine, like Montessori's, opposes to the ideas underlying the conventional methods of class-teaching a conception of educational activity much more free and natural; and it has had much influence upon educational thought and practice, more immediately in the United States, but in a less direct way also in Europe. In the United States it is expressed partly in efforts to bring the activities of school into as close relation as possible with those of the outer world; elsewhere it has helped to form the broader view that the school should be a place where the young may come into effective contact with the great cultural traditions that have shaped modern civilisation. Dewey's pragmatism has also done much to further the mode of teaching known in the United States as the "project method." By this term is meant that the scholar should acquire his knowledge, say in mathematics, science, geography, or history, in the attempt to achieve some interesting purpose or to understand how certain problems of practical and social importance are solved. To learn the rudiments of trigonometry in order to carry out a survey of the home district would be an instance of the project method.

*The "New School."*—The foregoing tendencies and ideas are reflected in many ways in the schools of Europe and America. In England there have been numerous educational experiments (*q.v.*)—some bold and even daring adventures in unconventionality, others more cautious, tempering the new ideas with what is soundest in the older traditions. The schools founded by Reddie (1899) and Badley (1902) were pioneers of a movement which, under the name of the "new school," has spread into several Continental countries. Among the "thirty points"

of the movement the more essential are that a "new school" is a boarding school, preferably for both sexes, that it should be in the country and be conducted as a free, co-operative society in close contact with nature, and that it should give a large place on the one hand to manual work, the cultivation of the soil and the breeding of animals, and on the other hand to the practice of the arts and the pursuit of science. Decroly's school in Brussels, whose programme has been in effect approved by the State, is a special type of "new school" in which the curriculum is presented through a study of primitive man. In England there are or have been schools (e.g., Oundle, under Sanderson) pursuing the main purposes of the "new school" by less unconventional methods.

**German Reforms.**—In the educational reforms in Germany a large part is played by the "activity schools" (*Arbeitsschule*) inspired by the veteran Kerschensteiner of Munich. The term meant originally a school in which manual work was the core of the curriculum, but its significance now includes "project" methods in all subjects. Service of the community is the objective of the education, and "creative learning" its fundamental principle—that is, learning motive by the pupil's own interests and initiative and his instinct for social co-operation. Under this scheme the timetable and the conventional division of the curriculum into subjects tend to disappear, for all instruction becomes "incidental." Accordingly, what is called "integrated instruction" (i.e., teaching which ignores subject-divisions) is largely the rule in the *Arbeitsschule*, and has even been, in some German states, prescribed by law for the first four school years. (See EDUCATION.)

**TEA ROOMS:** see FOOD SERVICE.

**TECHNICAL EDUCATION** (see 26.487).—The tendency in recent educational administration has been increasingly to focus phases of industry in particular institutions.

## I. IN THE BRITISH EMPIRE

The statutory duty of local education authorities to co-ordinate all forms of education within their area has led them, since 1909, to develop technical education by a progressive delimitation of the functions of rival schools. Secondary education (*q.v.*) and, to a less extent commercial education (*q.v.*) are being removed from technical schools and concentrated elsewhere; similarly, adult education (*q.v.*) now being developed at evening schools for men and women and at literary institutes, is being taken away, by degrees, from the technical schools to utilise accommodation for the teaching of scientific and technological processes.

In large centres of population, technical instruction is grouped around the major technical schools within the area, minor or junior technical schools being affiliated to a parent institution. In 1913, the evening school system of London was re-organised by the London County Council on these lines, and a similar re-organisation has been effected in other large towns. The present system is designed to encourage boys and girls on leaving the elementary schools at the age of 14 to enrol in junior technical schools or junior commercial schools for a course of study until the age of 17 or 18 is attained, provision being made by most authorities for trade scholarships at the age of 13 for children of exceptional ability. At the age of 17 or 18 the junior students can be transferred to the appropriate senior school, free places being awarded to those who have given promise of assiduity or ability.

The need, especially in rural districts, for the old type of elementary instruction for more or less illiterate adults has practically disappeared, and, in the opinion of the Board of Education, the tendency to concentrate classes and to reduce their number has on the whole been beneficial. In recent years, the function of evening schools has considerably changed; and, although the number of students has been diminished by schemes of re-organisation, a general raising of the standard of attendance and of work has been achieved. The modern type of evening school or institute is more closely in touch with industrial and commercial requirements than formerly, and the enrolment of serious students steadily increases, notably among women and girls by

reason of the development of trade schools for girls and of women's institutes.

**Special Schemes.**—In London and elsewhere special schemes have now been drawn up for technical education in textiles, mechanical and electrical engineering, chemistry, technical optics, architecture and the building trades, furnishing and furniture making, flour milling, retail distribution, banking and secretarial occupations, grocery and provision trades, and the boot and shoe trades. Recent advances include the institution of national certificates by the Board of Education in conjunction with professional associations dealing with mechanical engineering, chemistry and the gas industry, and the extension of the day training of apprentices in various trades, e.g., the rubber trades, music trades, printing and gas fitting. Consultative Committees have been appointed, either by the Board of Education or the local education authorities, to co-ordinate the details of technical instruction with trade requirements.

**Monotechnic Institution.**—The monotechnic type of institution has shown great potentialities in pushing forward education for specific trades, particularly in towns with a population or an industry large or important enough to support a technical institute of this type. Comparatively new industries have tended to go forward in education more rapidly than old industries, but, gradually, the application of scientific principles is extending through the medium of specialised technical training. Technical institutes in Great Britain may now broadly be divided into three categories:—(1) The monotechnic type which deals with everything in relation to one particular trade; (2) the polytechnic which provides instruction in practically all subjects of local importance; (3) junior technical schools and trade schools.

The monotechnic type of technical institute has achieved its greatest development in London, the largest institute of this type being the London School of Printing and Kindred Trades with 2,500 day and evening students. Other monotechnic institutions have been provided in London for the building trade, the meat industry, lithography, and photo-engraving, and for the leather and boot and shoe trades. Printing schools are also maintained at the *Ecole Estienne* in Paris, and at Utrecht, Brussels, Amsterdam, Zurich, Leipsic, Vienna and other European centres. Economic depression arising from the Great War restricted the development of technical education abroad. One effect of the War was a world-wide reaction in favour of the humanities, but later economic stress led to a more insistent demand for technical education.

**Canada.**—In Canada subventions have been voted for the improvement of technical and agricultural education, and in Denmark also development has been very largely in favour of agricultural education. In Australia technical education is being increasingly modelled on British lines. Lower commercial instruction has been organised in Norway and a number of agricultural continuation schools have been opened in Austria.

**Statistics.**—In England and Wales in 1922-3, there were 4,129 schools providing technical education. The enrolment at these schools was 659,936, of whom 23,317 were in day continuation courses. The enrolment was greatest in London which had an average of 4% of its total population under technical instruction; the average for the county boroughs was 2%, and for the administrative counties slightly over 1%. These percentages do not, however, represent the effectiveness of the instruction, since there is considerable divergence in local regulations governing the opening of classes and the attendance of students.

Post-War conditions caused violent fluctuations in the number of students receiving technical education. The highest attendances were recorded in 1921; subsequently economic duress and unemployment caused a decline, but in 1924 and 1925 enrolments began to increase again in many towns, notably in London which had an increase of nearly 20,000 students in two years in its day and evening technical and continuation schools. The average number of student hours worked by each student rises steadily; in 1923 it was 76 hours per student for the county boroughs, 61 hours for London, and 56 hours for the other administrative counties. The total public expenditure from rates and

taxes on technical education in Great Britain in 1925 was slightly over £3,000,000. For bibliography, see EDUCATIONAL LITERATURE.

(G. H. GA.)

## II. IN THE UNITED STATES

Agriculture was the first subject in which technical education was provided in the United States, because the country was long an agricultural country. The Congress of the United States made appropriations for agricultural education during the Civil War, and at later periods gave large grants to support schools of agriculture and divisions of agriculture in state universities.

Congressional support was extended in 1914 through the Smith-Lever law to what is known as agricultural extension. Under this law agents are distributed through the various states operating from the agricultural colleges, and promoting the development of popular courses in agriculture for adults and also courses in the high schools. The development of high school courses in this line has been so rapid that the colleges of agriculture find their student bodies seriously falling off in numbers because the subject-matter which they used to teach has been taken over by the high schools. The registration in all day agricultural schools under the supervision of the Federal Board for Vocational Education is indicative of the growth in interest in such courses at the secondary level. The details of this expansion are as follows:—

*Number of Pupils in all-day Agricultural Schools*

|                |        |                |        |
|----------------|--------|----------------|--------|
| 1918 . . . . . | 15,453 | 1922 . . . . . | 52,961 |
| 1920 . . . . . | 31,201 | 1925 . . . . . | 65,945 |

*Engineering.*—The development of engineering schools in the United States came much later than the establishment of schools of agriculture. In recent years, various types of engineering have come to be an important part of university curricula, especially in the great state universities of the Middle West and West. Furthermore, the larger cities have organised technical high schools in response to the demands of industry. These were originally thought of as schools for the training of mechanics. Experience has shown, however, that a relatively small percentage of the graduates of these schools actually work in the trades. Most of them enter upon higher careers as managers or follow the high school training by study in higher institutions. In the technical high schools and in the so-called mechanic arts courses of the ordinary high school, the pupils who are preparing to enter the trades usually remain only for one or two years. The short-period pupils in the technical courses constitute the group who are receiving what is commonly defined as industrial training rather than technical education.

*Part-time Plan.*—A method of relating theoretical training in the technical arts to practical operations in the world of industry was devised and first practised at the University of Cincinnati. This method is called the part-time plan, and provides for a periodical shift of students from school to factory and back again. The period of stay at school and factory varies in different institutions from one week to a month. Usually two equal groups of students alternate with each other, so as continuously to provide the industrial plant and the school with classes for the type of work which it is the share of each to contribute. The early experiments with the part-time plan demonstrated the necessity of a careful correlation of the work carried on in the two institutions concerned. The advantage of such a plan is that it releases the school from the necessity of equipping itself with the tools and machines demanded by modern mechanics. The learner gains the advantage of contact with current methods in industry and with the results of science. The plan is so successful that it has been imitated in commercial schools and in some of the lower industrial schools.

The larger industrial concerns have found that it is necessary for their success to carry the training of some of their employees to levels which equal those reached in college and university laboratories, and have accordingly established research laboratories and schools for the training of engineers.

The effort is being made on an increasing scale, especially in

urban centres, to train all the people in matters mechanical through industrial museums and exhibitions. The purpose of such institutions is to satisfy the popular desire for mechanical knowledge which has been stimulated by the extensive use of the automobile and the electrical contrivances and machines which are now common in homes. The successful example of Europe in this line has undoubtedly contributed to the development of such experiments in America.

(C. H. J.)

**TEETH:** see DENTISTRY.

**TEHRAN,** Persia (see 26.506), with a population of about 200,000, has, like the rest of Persia, seen little change. The Lalazar, the centre of the city, has some well-built shops, and in the suburbs are wide shady roads, lined with houses in large gardens. There are no factories except those for making carpets, but Tehran is one of the chief commercial centres of Persia, and an exhibition, with the object of increasing trade, was held in 1923. A police force, trained by Swedish officers, was organised in 1911 to try to enforce law and order in Tehran and southern Persia. The lightly metalled road from Tehran to Khanaqin on the Persian frontier, which was made by the British during the World War, has been kept up since by means of heavy tolls on traffic, and has become one of the main trade routes, as Khanaqin is linked with Baghdad by rail, and the northern trade routes have been closed. A road fit for light traffic has recently been made to the Caspian, and a motor service to Resht was started in 1924; it is also planned to metal the route to Bushire on the Persian Gulf, which carries a large proportion of the foreign trade, but is only a caravan track. No railway had been built to Tehran up to 1925.

**TEISSERENC DE BORT, LÉON PHILIPPE** (1855–1913), French meteorologist, was born in Paris Nov. 5 1855, the son of an engineer. He began his scientific career in 1880, when he entered the meteorological department of the Bureau Central Météorologique in Paris under E. E. W. Mascart. In 1883, 1885 and 1887 he made journeys to North Africa to study geology and terrestrial magnetism, and during this period published some important charts of the distribution of pressure at a height of 4,000 metres. In 1892 he became chief meteorologist to the Bureau, but resigned in 1896 and founded a private meteorological observatory at Trappes, near Versailles, where he carried out investigations on clouds and the problems of the upper air. In 1898 he published an important paper in *Comptes Rendus* detailing his researches by means of balloons into the constitution of the atmosphere. His discovery of the so-called isothermal layer, or stratosphere, as it is now generally called, will always stand out as one of the most important events in the study of the upper atmosphere. He also carried out investigations in Sweden and over the Zuider Zee, the Mediterranean and the tropical region of the Atlantic, and fitted out a special vessel in order to study the currents above the trade winds. He was elected a fellow of the Royal Meteorological Society in 1903, hon. member in 1909, and was awarded the Symons gold medal of the society in 1908. He collaborated with Hugo Hildebrandsson in *Les bases de la météorologie dynamique* (1900–5). He died at Cannes Jan. 2 1913.

**TELEGRAPHY** (see 27.510).—The two outstanding features in the art of telegraphy since 1910 have been (1) the widening application of printing telegraph systems, particularly those using the Baudot or five-unit code, and (2) development of carrier telegraph systems.

It has been found feasible to transmit alternating currents of frequencies as high as 30,000 cycles per sec. over open wire metallic return telephone circuits, and by means of thermionic valves or vacuum tubes to amplify the feeble received currents and retransmit or relay them into connecting circuits. As the voice range in ordinary telephone transmission requires only a band width of 2,000 or 3,000 cycles at the low end of this range, the remainder may be used for carrier telegraph and carrier telephone (see TELEPHONY).

A circuit from which telephone and direct current telegraph channels are derived, the telegraph employing the frequency range between zero and the lowest frequencies required for telephone purposes, is termed a composited circuit. The separation

is effected by means of simple electrical filters which are generally referred to as a "composite set." The compositing idea has been carried still further by superposing a high frequency carrier telegraph system upon a telephone circuit, the two being separated as before by more elaborate filters, which are sometimes referred to as a "high frequency composite set." A carrier telegraph circuit provided with equipment for utilising the alternating currents within the voice range for telegraph purposes is termed a "voice frequency carrier telegraph circuit."

#### METHODS OF TRANSMISSION

*Composite Telegraph and Telephone.*—Considerable advance has been made in the technical knowledge of simultaneous telegraph and telephone operation over the same wires. The fundamental idea was that of Van Rysselberghe of Belgium. By means of electric wave filters, consisting of condensers and inductance coils, a line circuit is bifurcated at the terminals into two circuits, one offering low impedance and attenuation to the low frequency telegraph signals and high impedance and attenuation to the higher frequency telephone currents, the other offering high impedance and attenuation to the low frequency telegraph signals and low impedance and attenuation to the higher frequency telephone currents. The telegraph may be operated as a two-wire metallic return circuit, or as two separate grounded circuits. The former is the method used on small gauge circuits in cables, whereas the latter is the standard practice for open wire lines. Fig. 1 shows the separating filters or, as they are termed, the

FIG. 1.—Schematic of Composite Set for grounded telegraph system.

"composite set." Where it is desired to use two telephone circuits in tandem to provide long telegraph circuits, the telephone circuits are connected together through intermediate composite sets which permit the telegraph currents to pass but effectively separate the circuits for telephone communication.

*Carrier Telegraph Systems.*—The greatest contribution to the art of telegraph transmission over land lines since 1910 has been the application of vacuum tubes and the electrical filter which have made practicable the carrier current systems. Two carrier systems have been developed, one the high frequency system for use on open wire lines over which it is possible to transmit alternating currents of frequencies above the voice range, and another system for use over land cable circuits, which utilises the voice range of frequencies and so is called the voice frequency system.

*High Frequency Carrier Telegraph System.*—The high frequency system has been designed for operation over one pair of wires. Transmission in both directions is obtained by dividing the band of frequencies available (3,000 to 10,000) at about 6,000 cycles, and using one portion of the band for east to west transmission and the other portion for west to east. This separation is achieved by suitably designed electrical filters termed "directional filters." To obtain a number of telegraph channels, it is necessary to split up these wide bands—3,000 to 6,000 and 6,000

to 10,000—into narrower bands, but still of sufficient width to enable telegraph signals of good quality to be transmitted. Within the frequency range mentioned, 10 telegraph channels in each direction are obtained. An east to west channel is associated with a west to east channel, thereby providing the equivalent of a duplex circuit. A carrier system thus provides the equivalent of 10 duplex circuits.

Each channel of a high frequency carrier system comprises a vacuum tube oscillator, tuned to a particular frequency, the steady output from which is applied intermittently by the actuation of the sending key or other transmitting device used. These trains of alternating current waves are amplified, pass through a tuned selective circuit, combine with the signals from other channels and thence flow into the line. At the receiving end they enter a selective circuit which, being tuned to the same frequency, offers a path of low impedance to them but a high impedance to all other frequencies. The signals are then amplified and rectified, the rectified signals actuating a relay. To separate the carrier currents as a group from the currents used for ordinary telephony and telegraphy, "high pass" and "low pass" filters are used. This combination of filters is sometimes called a high frequency composite set. To separate the voice frequency currents from the currents of still lower frequencies used for the ordinary telegraph circuits, the ordinary composite set is used.

Carrier circuits of this type provide high grade signals, are very stable in operation and are free from the balance troubles of direct current duplex systems. This system has enabled the following communication facilities to be obtained commercially from a single pair of open wires: 20 one-way carrier telegraph channels, 4 one-way direct current telegraph channels, and 1½ telephone circuits including the phantom.

*Voice Frequency Carrier Telegraph System.*—The heavy telephone traffic in thickly populated territories has led to the use of cable circuits in place of open wire lines. To provide telegraph facilities over such routes, it would not be possible to use the high frequency carrier system because of the great attenuation of high frequency currents in cable conductors. The need for such facilities led to the development of a carrier system using frequencies within the voice range. This system has been designed particularly for use over four-wire telephone circuits so that the same frequencies may be used in each direction. Although fundamentally the same principle as the high frequency system, this system differs in a number of details. One multi-frequency generator, furnishing currents of 12 frequencies from 425 to 2,295 cycles per sec., spaced 170 cycles apart, is the source of power, and is capable of feeding as many as 20 separate carrier systems, i.e., 240 carrier channels. The steadily applied carrier current of each channel is interrupted by actuation of the transmitting key or other sending device.

This interrupted carrier current passes through a sending band filter constructed as to permit relatively free passage of current of frequencies slightly above and below the carrier frequency for which it was designed. To currents of other frequencies it offers a high impedance, and this practically excludes them. After passing through the filter, the current combines with currents of other frequencies from the other channels and passes over the line as a composite current. As the over-all range of frequencies and the energy levels are about the same as those of telephone circuits, standard telephone repeaters are used to relay the currents. At the receiving end, the carrier currents are separated by a group of receiving band filters, each of which offers a low impedance path to a relatively narrow band of frequencies comprehending that of a particular carrier frequency and acts substantially as an open circuit to other frequencies. After passing through the receiving filter, the current is amplified and then rectified, the rectified or direct current signals actuating a relay. An east to west channel and a west to east channel are combined to furnish the equivalent of a duplex circuit.

The above description applies particularly to a system developed in the United States. In Germany a somewhat similar system has been developed. The German system uses a separate vacuum tube oscillator for each channel and interrupts the

carrier currents to form telegraph signals, no sending filters being used. At the receiving end, four-electrode vacuum tubes are used for amplifying and rectifying the signals. Over a four-wire circuit, six telegraph channels in each direction are provided.

**Direct Current Metallic Telegraph System.**—The increase in knowledge of the fundamental requirements of simultaneous telephone and telegraph operation has enabled a direct current telegraph system to be developed for operation over long small-gauge telephone cable circuits. This system is arranged for metallic circuit working using a relay operating with a current of

FIG. 2.—Schematic of Composite Set for metallic return telegraph system.

approximately two milliamperes. The general circuit arrangements of this system are shown in fig. 2. The cable circuit is divided by a composite set or filter into two branches, as has been described under *Composite Telegraphs*. All metallic circuits in a single office are supplied from a common battery. The type of sensitive polar relay, which was specially designed for this service, is shown in fig. 3. The relay is provided with four accurately balanced line windings and two additional windings for use

FIG. 3.—Polar relay for metallic return cable system.

in a Gulstad vibrating local circuit. The armature is a reed, fixed at one end, and forms the cross piece of a magnetic bridge. The six windings surround the armature. Current in one direction causes that end of the armature carrying the contacts to move towards one pole, and current in the opposite direction causes it to reverse its motion.

#### PRINTING SYSTEMS

**Creed System.**—This system, which came into use early in the present century, has been improved by simplification of apparatus units and elimination of need for air pressure. The new ma-

chines are actuated electrically and are capable of operating at much higher speeds than the earlier models.

**Baudot.**—Use of the Baudot multiplex printer system has been widely extended in Great Britain, and the system modified by British engineers. It has been duplexed, thereby doubling its traffic carrying capacity. Transmission is controlled by perforated tapes actuating automatic transmitters, instead of by direct keyboard operation, thereby permitting the rate of operation to be increased about 50%. Electrical vibrating reeds and phonic wheel motors are used to drive the distributors, ensuring stable synchronism.

**Murray Multiplex.**—This system of multiplex is based on the Baudot. Operators prepare messages by perforating paper tapes by means of keyboard perforating machines having a keyboard similar to a typewriter. Each key of the machine, when depressed, perforates a particular combination of holes in accordance with

FIG. 4.—Murray multiplex tape, showing perforations for word "TELEGRAPH."

the arrangement of the five-unit code adopted by Murray. Fig. 4 shows a portion of tape perforated to transmit the word "telegraph." From the perforating machine the tape passes directly into an automatic transmitter which has five selecting pins, each controlling a contact lever resting normally against a busbar connected to the spacing pole of the line battery. When a selecting pin passes into a hole in the tape, the associated contact lever moves over and makes contact with a busbar connected to the marking pole of the battery. The positions of the contact levers are therefore determined by the perforations in the tape. Each lever is connected to its own particular segment on the sending ring of the distributor, the five segments associated with a transmitter usually being placed in sequence around the ring, so that as the brushes pass over the segments a particular combination of signals representing a letter, comprising positive and negative impulses, is sent out to line. Immediately the brushes have passed over the last of the segments associated with a particular transmitter, a local current impulse is sent from another ring of the distributor through a "cadence" electromagnet in the transmitter, which when operated withdraws the selecting pins, feeds forward the paper tape and sets up the next letter combination. Provision is made to prevent the transmitter overtaking the perforating operator by causing a taut tape between the two machines to move a light lever and so open the circuit of the "cadence electromagnet," thereby stopping the operation of the transmitter. As soon as the tape slackens the lever is restored to normal and the transmitter starts again.

**American Multiplex Systems.**—The Western Electric and Western Union Telegraph companies jointly developed a multiplex printer system primarily to meet the needs of the Western Union Telegraph Company. It resembles the Murray system as regards use of keyboard perforators, rotating distributors and page printers, but differs from the Murray in many details. Instead of transmitting extra signals per revolution of the distributors to maintain synchronism, correcting impulses are generated from the character signals, thus saving line time. A large vibrating fork is used to drive a phonic wheel motor, which is the motive power for the distributor. Various types of printer units have been successfully used with this system. All circuits are operated duplex, and double, triple and quadruple channel systems are in service. Speeds as high as 50 and 60 words per min. per channel are maintained by operators. Another American multiplex printer system has been developed by the Morckum-Kleinschmidt Company. This system does not differ radically from that described above except for the utilisation of cam-controlled contacts in place of segmented ring distributors with rotating contact brushes.

**Siemens and Halske Automatic System.**—This system is a single channel high speed synchronous printer system, using a five-unit code. At the sending end the operations are practically identical with those of the Wheatstone, Creed and Murray Automatic. A number of operators prepare perforated tapes which are passed to an operator who feeds them into the transmitter. The hole combinations are arranged across the tape as in the Murray multiplex, but the tape has two rows of feed holes, one along each edge. The tape is not stepped forward but moves uniformly, the transmitter being geared to the distributor brushes. No special signals are transmitted to maintain synchronism, correcting impulses being derived from the message signals. When no messages are being sent, provision is made for sending a signal once per revolution to maintain synchronism. The sending distributor brush arm is driven by a shunt wound motor, having a heavy flywheel mounted on the same shaft.

The receiving and translating arrangements of the receiver are almost entirely electrical. The brush arm of the receiving ring is mounted on the same shaft as the typewheel. The exact position of the typewheel when the paper tape is momentarily pressed against it to print a letter is determined by the particular signal combination set up in one or other of two groups of storing relays. Synchronism is maintained by varying a resistance in the field of the driving motor of the distributor. The printed tape is pasted on message forms, as is the practice with all tape printing machines. Provision is made for receiving messages as perforated tapes by associating one of the keyboard perforators with the receiving ring segments. The system may be worked simplex or duplex, and is capable of operating at a maximum speed of 1,000 letters per min. in each direction, *i.e.*, 166 words in the English language.

**Start-Stop Printer System.**—A "start-stop" system is one which provides for the transmission of one message over a circuit, or, when duplexed, one message in each direction simultaneously. The term "start-stop" has been adopted because the distributor brush or equivalent rotating mechanism is started and stopped once per revolution. Start-stop sets are in wide use in the United States, where several types have been designed. One type comprises a keyboard transmitter, a motor-driven brush distributor and a printer. In some cases the keyboard is arranged to control a perforator, so that messages may be transmitted either direct from the keyboard, or set up as perforations in a tape and so control the operations of an automatic transmitter.

The distributor brush arms (one on each face of the distributor), driven through a friction clutch, are normally held stationary by a latch and make one rotation for each character transmitted or received. The start impulse releases the sending start-latch and actuates a relay at the distant station to release the receiving start-latch, so that if the rotation speeds are approximately the same the transmitted impulses are distributed properly to the selecting magnets or elements of the printer at the receiving station. In duplex operation, the sending brush arm and receiving brush arm rotate independently of each other. Close synchronism is not required, since the distributors are stopped and caused to start from the same initial position for each character. This feature automatically takes care of line lag and renders the system well adapted for use on circuits having a number of stations operating simultaneously. These systems have been used to a considerable extent over telegraph circuits obtained from telephone circuits and have a maximum speed of about 360 letters or characters per minute.

Another type of set has a battery of cams mounted within the printer to take the place of the brushes and segmented rings of the distributor. Either a page printer capable of operating at 360 letters per min. or a tape printer at about 270 letters per min. may be associated with this set.

**Cipher Printing System.**—A printing system for rapidly enciphering and deciphering telegraph messages has been developed by the engineers of the American Telephone and Telegraph Company. It was successfully applied by the U.S. Army Signal Corps during the World War, when enciphering and deciphering were performed with increased speed and accuracy.

**Gulstad Relay.**—In 1898 Gulstad of Copenhagen invented a modified form of polarised relay known as a vibrating relay, the use of which has enabled much higher speeds of working to be attained on all types of telegraph circuits using polar or double current transmission. The principle of the relay may be understood by referring to fig. 5. It will be seen that the ends of the local windings are joined to terminals B and C and their centre to terminal A, which is connected through an adjustable resistance Y to the relay tongue. This resistance is for regulating the local current so that the magnetic effect produced thereby is less than that produced by the steady line current through the line windings. Terminal B is connected to ground through a condenser K and terminal C through a resistance X. Generally, resistances X and Y are made equal.

FIG. 5.—Schematic of connections for Gulstad relay.

Assuming that there is no current in the line windings and the relay tongue has just reached the contact M (Marking), there will then be a momentary rush of current through the winding AB to charge the condenser K, in a direction to keep the tongue to the marking side, thus preventing any tendency of the tongue to rebound. This charging current quickly ceases as the condenser becomes charged and directly its intensity falls below that of the current flowing through the winding AC, the preponderance of the latter causes the tongue to move toward the spacing contact S. Immediately the tongue leaves the marking contact, the condenser K discharges through both windings BA and AC in such a direction as to accelerate the movement of the tongue, so that its transit time from one contact to the other is thereby lessened.

When the tongue reaches the opposite contact, the condenser K is again charged, but this time from the other pole of the battery; a similar cycle of effects therefore takes place on that side, and the tongue moves in the reverse direction. In this manner the relay tongue is kept vibrating at a speed depending on the values given to the condenser and resistances and the distance of travel of the tongue between its contacts. In practice, the adjustments are such that the rate of vibration of the tongue under the control of the local current is approximately equal to the rate at which the transmitter at the distant station sends reversals at working speed. When this obtains, the signals passing through the line windings merely determine the length of time that the tongue remains in contact with either stop, its movement therefrom being effected by the local current through the local windings as soon as the strength of the line current falls below that of the local current in the winding AC.

**Interference.**—Ground return telegraph circuits are subject to three sources of interference which impair or degrade them,

namely, induction from AC power lines, induction from other telegraph circuits along the same route and differences of direct current earth potential between the terminal stations. In the first case, where the frequency is not too close to that of the telegraph, the interference can be considerably reduced by the provision of tuned drainage shunts, high impedance anti-resonant series devices and by reducing the responsiveness of the receiving circuits to the interfering current by balancing arrangements. Where possible, it is usually preferable, however, to locate and eliminate the source of the induction. This is particularly true in the case of high-speed telegraphs, where the above methods are generally inapplicable. In the second case, the interference is usually mutual between several conductors and is more generally experienced on cable circuits. This interference can be greatly diminished by coupling the duplex sets together by means of condensers and transformers so as to neutralise the current introduced through coupling between the lines. The effect of local ground potential differences can be overcome by supplying a counter electromotive force from a special generator automatically adjusted for neutralisation.

## STATISTICS

The following table gives the miles of telegraph wire throughout the world, Jan. 1 1924 and 1910.

**TELEGRAPHY, SUBMARINE** (see 26.527).—Improved methods of working have been introduced and apparatus has been invented with the object of increasing speed and reducing error in transmission and reception.

*Signalling Difficulties.*—One of the factors which limit the speed of signalling over a submarine cable of any considerable length is its inductive capacity due to which the impulses forming the letters, which are transmitted into the cable lose their definition and appear at the receiving end distorted and attenuated in what might be described as a spread out condition. The maximum speed of signalling is therefore that at which it is possible to distinguish between the various impulses or sets of impulses in order to make the signals readable.

The siphon recorder is still the instrument generally employed for recording these signals, but whereas in the past the messages were written up by hand, the recorder is now usually employed for watching the shaping of the signals and for adjustment purposes, the signals actuating a train of automatic apparatus by which the messages are typed or printed. By the introduction of appropriate capacity and inductance into the sending and receiving circuits it is possible to improve greatly the received signals which although reduced in size are much more clearly defined, thus allowing an increase in the speed of transmission.

*Magnifiers.*—By the use of a magnifier the received signals can be increased in size and, in turn, the speed of transmission may again be raised. Magnifiers can seldom be employed to their full advantage on account of imperfections in the duplex balance and local disturbances due to induction from other circuits and electric tramways or power mains, but their introduction usually permits an increase of speed of about 30%. In order to minimise the disturbances compensating devices are employed necessitating the use of twins or tricone shore-end cables, the actual point of earthing the circuit usually being some miles out at sea. Several forms of magnifier are employed which depend on the movement of a suspended coil as in the case of the siphon recorder, but the movement is utilised to bring about the operations described hereafter instead of deflecting the glass tube. An ordinary siphon recorder is usually employed in conjunction with the magnifier to register the resulting signals.

*The Heurley Magnifier.*—This operates by upsetting the equilibrium of a Wheatstone bridge balance, two arms of which are composed of extremely fine wires. The wires carry current and, in the earlier form of the apparatus, are moved by the action of the coil so that they become immersed in or shielded from a current of air. The resulting change in temperature causes an alteration in their resistance values and thus affects the recording instrument connected in the cross circuit of the bridge. In a

later form a pair of hot wires carrying current are moved towards or away from a similar but fixed pair thus varying their temperature and in consequence, their resistance.

*The Judd and Fraser Magnifier.*—This instrument depends on the movement of an electrode between two fixed ones immersed in an electrolyte such as dilute sulphuric acid. The resistances of the electrolyte between the moving and fixed electrodes form two arms of a Wheatstone bridge the remaining arms being adjustable resistances. Thus, any displacement of the movable electrode from its symmetrical position between the fixed ones consequent upon deflection of the suspended coil has the effect of upsetting the balance, thereby causing a current to flow through the coil of the recording instrument which is connected in the cross circuit of the bridge.

In order to avoid the production of gas and a polarising of the electrodes the current which is passed through the electrolyte is an alternating one. This is brought about by the use of an electrically driven reed carrying a contact head so designed that the positive and negative poles of the battery are rapidly reversed. Simultaneously the current in the recording instrument is rectified by means of a second set of contacts mounted on the same reed. A blocking condenser is included in the circuit to prevent the passage of any direct current through the electrolyte. In a later form a three-electrode valve and transformer are introduced to amplify further the current before rectification.

*The Cox Magnifier.*—In this type a specially constructed selenium cell is divided into two sections which form two of the arms of a Wheatstone bridge. A beam of light is passed through a metal comb and reflected on to the cell by a small mirror mounted on the suspended coil. A deflection of the coil causes one portion of the cell to become darkened and the other to become increasingly illuminated thus bringing about a change in the resistance values of the two sections of the cell and operating the recording instrument or relay in the cross circuit.

*The Orling Magnifier.*—A jet of liquid, such as acidulated water, is deflected by a fine wire attached to the suspended coil, which wire intersects or penetrates the stream. A slight movement of the coil and wire will cause a considerable deflection of the stream which may complete a recorder circuit by coming into contact with one or other of the two conductors situated one on each side of the initial and normal position of the axis of the stream. Alternatively, the stream when deflected may provide a temporary bridge between one or the other of the two pairs of contacts.

*Thermionic Valves.*—These have also been used very successfully in connection with cable circuits for amplifying purposes.

*Relays (Repeaters).*—If, instead of tracing the signals by means of a glass tube as in the case of the siphon recorder, the moving coil be employed to make electrical contacts, retransmitting apparatus taking current from a local battery may be operated, thus repeating the weak incoming impulses into a second cable as strong signals. An instrument of this description is known as a relay and on a long cable such an instrument may be used in conjunction with a magnifier. The speed at which a cable may be worked depends very largely on its KR, this being the product of its inductive capacity (K) expressed in farads and its ohmic resistance (R). It is, however, dependent to a certain extent on the voltage employed for transmitting, an increase giving a somewhat higher speed. It is usual to consider that the speed at which cables may be worked varies inversely as their KRs and if, therefore, a cable, say, 3,000 m. in length and having a KR of 6 could be diverted into an island situated half way along, the KR of each section would then be 1.5 since both the resistance and capacity values are reduced by one-half. The through speed of working could then be increased four times if an automatic relay were installed at the intermediate station.

Relays by Dr. Muirhead and S. G. Brown are in considerable use and the "Jockey" relay introduced by the Eastern Associated Telegraph Companies is now almost exclusively employed in their service. This relay permits of the use of ordinary shaping conditions and does not, as in other cases, necessitate the use of an unshunted receiving condenser in the coil circuit in order to

block out earth currents which would otherwise involve a disturbance of the zero position of the coil thus causing bias or thickening of the signals on one side and thinning on the other.

When an unshunted condenser is employed to obviate this trouble a "local correction" is necessary to counteract the overcurbing or falling away of the received signals consequent upon the use of the condenser. This is usually applied by means of a second winding on the suspended coil, the current through which is adjusted to vary at the correct rate and strength to hold up the signals. With the "Jockey" relay a correction of this sort is unnecessary since by the use of a resistance shunt over the receiving condenser the overcurbing or falling away of the signals is obviated. The relay contacts are mounted on a frame suspended on a pivot and free to move as the contact tongue attached to the main coil is deflected by the earth current. The frame or "jockey" carrying the contacts is so damped by means of vanes immersed in oil that it is not displaced under ordinary signalling impulses but is nevertheless able to respond to the relatively slow changes of coil zero brought about by earth current variations, thus keeping the contacts symmetrically disposed with regard to the contact tongue operated by the coil.

*Bruce Relay.*—In a relay introduced by W. M. Bruce, a contact tongue attached to the suspended coil rests on a revolving drum divided into three insulated contact sections as in the case of S. G. Brown's relay. Each of the two outer sections with which the tongue makes contact when the coil is deflected to one side or the other, is connected to the grid of a three-electrode valve in the anode circuit of which the windings of a translating device or relay are included. Since it is only necessary to transmit potential to the grids in order to allow of the passage of anode currents to operate the translating device, the resistance of the contact between the tongue and revolving drum is not of great importance, and light contact pressure may be employed, thus reducing the mechanical damping of the coil and allowing of increased speed of signalling.

*Automatic Working.*—Automatic working has resulted in a very great reduction in the time of transmission of traffic and also in improved accuracy. The monthly statistics carefully compiled by the Eastern Associated Telegraph Companies show that the error percentage for automatic working is approximately one-fifth to one-sixth of that for manual working and except for the initial operation of preparing the perforated tape for transmission the system adopted on nearly all main line cables is entirely automatic. As an example, a message handed in in London is dealt with by an operator who by means of a perforator, the keyboard of which resembles that of a typewriter, prepares a perforated paper tape which is run through a transmitter thus sending into the cable electrical impulses corresponding to the perforations in the tape. These signals are automatically repeated by apparatus installed at the various stations along the route so that a message for Australia, India, South America or China arrives at its destination without any further reperforating or retransmitting by manual means. At the terminal station an automatic perforator produces a tape which is a replica of that originally prepared in London. This in turn passes through a printer which types out the message in the form in which it is delivered.

*Distortion Effect and Remedy.*—The signals received from a cable of any considerable length when working at a speed approaching the maximum, are somewhat distorted and it is undesirable to retransmit these signals through a number of cables linked together by relays since the distortion is cumulative. Certain stations along the route are therefore provided with automatic receiving perforators in place of simple relays so that a perforated tape is prepared and immediately passed through a transmitter thus sending perfect signals into the next cable and thereby ensuring accuracy and avoiding a reduction in the through speed of transmission.

*The Regenerator.*—The delay introduced by this method of working, known as tape-translation, is small but the recent advent of a system of retransmission employing an instrument known as the "Regenerator" allows of the direct linking up by

relays in conjunction with this apparatus of a greater number of cables, thus decreasing the total delay as well as reducing the chance of error by the retransmission of perfectly corrected signals at each stage. The comparatively large tolerance of the regenerator for correctly interpreting distorted signals depends to a great extent on the fact that it is running at exactly the same speed as the transmitter at the distant end of the cable; further, it is also able to follow any slight alteration in the speed of transmission. This is effected by taking the average time of arrival of the signals and comparing it with a predetermined position of a point on the shaft of the retransmitting apparatus. If this time differs, corrections are caused to occur to increase or decrease either momentarily or permanently the speed of the shaft so as to maintain the operative parts on the shaft in constant relation to the incoming signal. Special precautions are, however, taken to ensure constant speed and both transmitting and receiving instruments are run by phonic motors which are controlled by electrically driven reeds or tuning forks. Although the frequency of vibration of the type of reed employed is for nearly all practical purposes constant, a high grade electrical clock is in many cases used to control the reed in order to eliminate any small variation due to temperature changes or other causes.

*Performance.*—As an example of the speed of transmission, His Majesty the King's message comprising 12 words announcing the opening of the British Empire Exhibition at Wembley on April 23 1924 was flashed round the world by the submarine cable systems in 80 seconds. The route was as follows:—

The Stadium-Penance-Fayal-Halifax by the Imperial (British Government System). Halifax-Montreal-Vancouver-Bamfield-Fanning-Suva-Auckland-Sydney by the Pacific Cable Board's system. From Sydney by two routes, both of the Eastern Associated Companies' system as follows: (1) Sydney-Adelaide-Perth-Cocos-Rodriguez-Durban-Cape Town-St. Helena-Ascension-St. Vincent-Madeira-Portsmouth-London. (2) Sydney-Adelaide-Darwin-Singapore-Madras-Bombay-Aden-Suez-Alexandria-Malta-Gibraltar-Portsmouth-London. The messages arrived in London simultaneously at 11:50-55 A.M. having been despatched from the Stadium 80 seconds previously at 11:49-35 A.M. The total distance traversed via the South Africa route was, in round numbers, 32,300 m. made up of 26,000 m. of cable and 6,300 m. of landline. By the Indian route the total was 30,000 miles including roughly 8,200 m. of landline.

At the end of 1924 there were some 3,500 submarine telegraph cables in operation, having a total length of over 332,000 nautical miles, approximately 77,700 m. being administered by the various governments and the remainder by private companies. Of the latter approximately 144,000 m. are owned by British Companies, 83,000 m. by American Companies and the remainder by Companies of other countries. Since the above date several additional cables have been laid and no less than 26,000 m. were contracted for in the twelve months following June 1924.

*Superposing.*—By means of a system introduced by Dr. Pernot and L. Rich three messages are transmitted simultaneously over submarine cables and good results have been achieved on one approximately 1,100 m. in length. The cable is worked duplex in the ordinary manner and in addition, signals are transmitted in one direction by means of an alternating current of a frequency of the order of 40 cycles per second. The direct current for the ordinary duplex working is provided by a small motor-generator the generator field of which is excited from a battery joined up through the contacts of an automatic transmitter. Connected in series with the armature of this generator is the stator of a small alternator the field of which is energised from a battery through the contacts of a second transmitter.

Suitable tuned circuits and filters are included in the circuit at the sending and receiving stations in order to avoid interference and to separate out the alternating and direct currents. The former are amplified by means of thermionic valves and eventually operate ordinary telegraphic apparatus as employed for direct current working. This system which is a form of "wired wireless" was first installed with very satisfactory results on one of the Eastern Telegraph Company's cables between Gibraltar and Malta.

*The Loaded Cable.*—The submarine cable of the future undoubtedly will be of the new loaded type. The number of words

per minute that can be sent through an ordinary submarine cable is limited owing to the signals being distorted as they pass through the cable, so that at a certain speed they become unreadable. In the loaded cable this distortion is very largely eliminated and on a long cable a working speed in one direction of as much as ten times that of an ordinary cable of similar length may be attained. The loaded cable is so named because of its peculiarities being similar to a certain mechanical analogy. The ordinary cable can be likened to a light rope stretched tightly in water and the process of signalling to lateral movements at one end that cause waves to pass along the rope. These waves will rapidly diminish in size due to the friction of the water, but if the rope be weighted or "loaded" with weights at short intervals, the waves will travel along the rope with much less loss of size, owing to there being more energy associated with the waves. The loading of a cable is obtained by increasing its inductance or electrical mass.

One method of accomplishing this is to insert at intervals along the cable loading coils comprising an insulated conductor wound around a metal that will become magnetised when a current is passing through the cable and winding. The insertion of these coils presents mechanical difficulties, especially where the cable is to be laid in deep water as would usually be the case where a long cable is concerned, and the necessity for an increase of speed most apparent. It may, however, be possible to introduce inductance in this form, known as "lump loading" into existing cables which are not laid in very deep water. The possibilities of loading have been realised for many years, and cables loaded with soft iron wire were laid over twenty years ago for telephone purposes. The small increase of inductance due to soft iron makes it unsuitable for use for long telegraph cables and it is the recent development of nickel-iron alloys that has made the loaded telegraph cable a successful project. (See TELEGRAPHY.)

*Continuous Loading.*—The introduction of these nickel-iron alloys of high permeability for low magnetising forces has made it possible to employ "continuous loading" which does not alter the present regular form of the cable or add to the difficulties of laying or raising for repair. This alloy is employed in the form of a fine wire or tape which is wound continuously and directly around the copper conductor before the gutta percha insulating sheath is applied. The first telegraph cable of this description was manufactured in England and laid for the Western Union Telegraph Company in Sept. 1924 to connect New York with Horta in the Island of Fayal, Azores. Another cable was laid in March 1926 for the Eastern Extension Company to connect Cocos Island with Perth, Western Australia.

A cable of this type can work at a very high speed when compared with an unloaded cable of the same length and having similar weights of copper and gutta percha per mile. On such a cable the actual speed in letters per minute attainable is above that of any automatic receiving apparatus at present available for directly printing the received traffic or for producing a perforated tape which can be utilised for operating a printer. The use of receiving apparatus comprising thermionic valves and a specially constructed high speed siphon recorder would necessitate the introduction of a manual operation for preparing the message for retransmission or delivery, such as perforating, writing or typing from the tape on which the signals are recorded and this would undoubtedly result in delay and increased percentage of error.

It therefore appears likely that a multiplex system such as employed on fast landlines will eventually best meet the requirements, so that several messages will be transmitted to all intents and purposes simultaneously. For example, by adopting the Baudot or similar system it would, no doubt, be possible to operate a number of channels up to say, six, each dealing with about 40 words per minute.

Experiments are also being made with a view to the simultaneous transmission of signals by alternating currents at different frequencies, these being separated out at the receiving end by means of tuned circuits and filters. The problem of "duplexing" a loaded cable presents a number of difficulties but

research work is being carried out with a view to the production of a satisfactory "artificial line" to copy as nearly as possible the characteristics of the cable. (J. D.-P.; N. C. G. W.)

**TELEKI, PAUL**, COUNT (1879–1940), Hungarian politician and geographer, studied jurisprudence and geography in Budapest. After being elected to Parliament in 1905 he spent some years in geographical study abroad, and published *Atlas zur Geschichte der Kartographie der Japanischen Inseln* (Budapest, 1909), which was crowned with the Prix Jomard by the French *Société de Géographie*. During the early part of the World War he served as an automobile officer in the campaign against Serbia and found time to prepare a handbook on *The History of Geographical Thought* (1917). When the revolution broke out he retired from public work and produced a number of ingenious maps showing the national minority problems and economic situation of Hungary. Teleki organised the scientific side of the preparations for the Peace Conference, making an exhaustive and enlightening exposition of the Hungarian case. He was appointed Minister for Foreign Affairs in the first parliamentary cabinet of Admiral Horthy, the Regent (April 1920), and in July of the same year became Prime Minister. He resigned in 1921 after the first attempt of King Charles to regain his throne. Later in the year he was appointed professor of economic geography in the University of Budapest. In 1924 he served in a scientific capacity on the commission appointed by the League of Nations to enquire into the Mosul frontier dispute between Great Britain and Turkey.

Teleki's works include, besides those already mentioned, *The Evolution of Hungary and Its Place in European History* (New York, 1923); *Ethnographical Map of Hungary* (1920); *Economic Geography of America* (1922, Hungarian).

**TELEPATHY:** see PSYCHICAL RESEARCH.

**TELEPHONY** (see 26.547).—The steady sequence of improvements in exchange cable which began with the installation of the first cable of this type in 1882 has, in the years now under review, included a 900-pair, 22-gauge<sup>1</sup> cable in 1912; a 1,200-pair, 24-gauge in 1914; followed by the 450-pair, 19-gauge cable in 1918, which because of the large size conductors it contains is being extensively used for the building of long toll lines, as will be mentioned in the paragraph *Long-Distance Telephony by Cable*. These increases in the number of conductors—increases of from 200% to 500% over the original value—have all been accomplished without any increase in the outside diameter of the sheath, which still remains, for the largest sizes, at 2½ inches. Along with these increases in number of conductors has gone a notable decrease in the first cost per mile of installed cable conductors. The same developments are also making possible corresponding economies in all smaller sizes of cable which, because of fewer conductors, do not require the maximum size of sheath. A change in cable sheath material has also been effected which makes possible an equally durable sheath at a lower cost. The new sheath consists of lead alloyed with 1% of antimony instead of 3% of tin as formerly.

*Telephone Repeaters*.—One of the outstanding achievements of the period 1910–26 is the development of long-distance wire telephony to the point that the voice can be carried over practically any terrestrial distance. In this advance the telephone repeater has played a dominant part. The repeater in its present form employs the three-electrode thermionic vacuum tube as the amplifying agent for telephone currents and also includes balancing networks, electric filters and means for controlling amplification, their association calling for great precision of design and manufacture. The first and one of the most notable achievements, employing the thermionic telephone repeater, was the opening for public service, in 1915, of the telephone line between New York and San Francisco, a distance of some 3,400 miles.

In 1921, in order to cope with an increasing demand for transcontinental service, the loading coils were removed from this line and repeaters of an improved type were applied in place of the original six. This change made the circuits suitable for the application of carrier current facilities, and also resulted in a

large improvement in the clearness and volume of transmitted speech. The four wires of the original transcontinental line now furnish three telephone circuits and, over certain sections, as many as 20 telegraph circuits. Some picture of the accuracy and amplifying power of the telephone repeater can be gathered from the fact that, in passing from New York to San Francisco, the voice current is amplified over a million-million fold and yet arrives with all the clearness and intelligibility with which it starts.

*Long-Distance Telephony by Cable*.—As the demand for long-distance telephone service increased, it was foreseen that ultimately the need would arise for an improved type of long-distance circuit offering increased electrical stability and increased immunity from damage and disruption by storm. Moreover, large densities of traffic made desirable a long-distance circuit more compact physically than those in use. Accordingly, research was undertaken along various lines with the object of removing the restriction which had always limited the use of cable circuits to relatively short distances. The success of these researches is attested by the long telephone cable (over 900 m.) which has been completed between New York and Chicago at a cost of \$25,000,000. It supplies approximately 250 telephone channels and 500 telegraph channels. Among the developments which have made this cable possible are: improved designs of cable, improved methods for minimising capacity unbalance, means for automatically controlling the amplification of repeaters (as the resistance of the wire circuit to which they are attached varies with temperature), new and very compact types of telephone repeaters and other office equipment and new systems of telegraphy. One system of land cable telegraphy employs a unidirectional line current of about 1/20th the magnitude of the current employed in the standard grounded telegraph circuits; and another, known as "voice frequency" carrier telegraphy, supplies 10 duplex channels in the frequency band required for a single speech channel. New systems of loading designed to reduce "transient" and "echo" effects have also contributed to the success of the cable. In this connection, it may be pointed out that whereas it has become economically desirable, as noted in a preceding paragraph, to remove all loading from certain long, open-wire lines, nevertheless long cables depend upon loading because of their intrinsically higher attenuation.

*The Echo-Suppressor*.—One of the many novel developments underlying the successful long-distance cable is the "echo suppressor." In talking over very long cable circuits an appreciable interval of time exists between the uttering of the speaker's words and the return of reflected transmission or the "echo" to his ear from the distant end of the cable. This time interval is in the neighbourhood of 1/10 of a second and early investigations showed that, to the average telephone user, appreciable echoes having such a delay are not only very noticeable but extremely confusing. The voice-operated echo suppressor was, therefore, devised automatically to restrict transmission on the circuit to one direction at a time. The long telephone cable, possessing a high degree of electrical stability and placed either underground or on heavy poles, is a type of long-distance trunk line which will become increasingly important in the future, particularly between large cities.

*Carrier Current Telephony and Telegraphy*.—From the earliest days of both the telephone and the telegraph there have been many attempts to develop methods for the multiplex transmission of messages employing relatively high frequency currents as "carriers." It was not until the development of the thermionic vacuum tube, however, that carrier systems were brought within the realm of practicability. These tubes are used in carrier systems as repeaters or amplifiers, as generators of the different carrier frequencies and as "modulators" and "demodulators" for respectively combining the messages with and separating them from the carrier currents.

These systems also employ extensively another important device which was given to the electrical art contemporaneously with the vacuum tube repeater. This is the electric wave filter.

<sup>1</sup> The wire gauge here referred to is A.W.G.

This remarkable device can be so designed as to select any predetermined band of frequencies, rejecting all others without absorption. The rôle that the filter plays in carrier systems as a means of separating one message from another is therefore obvious.

Both carrier telephone and carrier telegraph systems have been extensively applied since 1918. When multiplexing a pair of telephone wires, it is customary to add either three or four high frequency channels to the voice frequency channel, thus increasing the message capacity of the wires either four or five fold. In the case of carrier telegraphy, the message capacity of a wire circuit may be made much larger and systems are in use in which as many as 10 to 20 carrier frequency channels are placed upon a single pair of wires. The shortest length of line which it is now economical to multiplex with carrier facilities lies between 150 and 200 m.; but it is expected that as further improvements and simplifications are made, the limiting distance will be brought down to a much lower figure.

*Transmission Measurement and Maintenance.*—The successful maintenance of vast networks of long-distance telephone circuits, both open wire and cable, has in large measure been made possible by the development of accurate means for making transmission measurements. Great success has been attained in the development of measuring apparatus, which, although of an exact and complicated character, is so simple of manipulation as to be used continuously in extensive daily programmes of routine measurements. In this apparatus, use of vacuum tube amplifiers permits the measuring of minute quantities by instruments that are rugged and, wherever necessary, readily portable.

*Radio Telephony.*—Since 1911 the entire growth, if not the actual birth, of the radio telephone art has taken place. Like the developments in carrier systems this rapid progress has been largely due to the high standards attained in the design and manufacture of thermionic tubes. An early radio telephone achievement was the transmission of speech across the Atlantic Ocean in 1915. The development of radio telephone apparatus was undertaken during the World War for such purposes as continuous communication between observing aeroplanes and artillery stations behind the lines, and between the units of a destroyer flotilla.

Following the War, public interest in the possibilities of radio telephony was quickly awakened, with a consequent rise of broadcasting (*q.v.*). The development of radio telephony for commercial message uses may appear, in contrast to the rapid strides of broadcasting, to have lain dormant. However, notable progress has been made. Immediately following the War, the development of radio systems for establishing ship-to-shore telephone communication began. In 1920 an experimental system was demonstrated by American telephone engineers which enabled a passenger on a ship several hundred miles at sea to communicate with any telephone subscriber on land through the latter's regular instrument. To accomplish this, the message was carried over the water by radio and at a coastal station was relayed to the land lines, which, in the case of one demonstration, were 4,000 m. long. The system was entirely two-way in its operation, in that it permitted the telephone subscriber and the person at sea to hold a conversation exactly as over the usual telephone circuit. Thus far no very extensive installation of ship-to-shore radio telephony has been made, largely because of the numerous commercial difficulties involved, although a limited service of this sort is, it is understood, offered by some German steamships.

*Transatlantic Radio Telephony.*—In 1920 a serious study of transatlantic radio telephony was undertaken. The difficult character of the technical problems involved may be inferred from the fact that, due to the extreme variability of atmospheric conditions as they affect the transmission of radio signals, the sending power required to produce a given effectiveness of received signal may increase by several thousand times within the space of a few hours. To ensure even reasonably reliable communication at all times of day and throughout all seasons of the year, therefore, necessitates transmitting stations of large reserve power and special receiving systems to reduce the interfering noise arising from atmospheric disturbances.

Another difficult requirement to be met is that the transoceanic radio link must automatically relay messages to and receive messages from the wire lines in both Europe and America, so that it will be as easy for two telephone subscribers, wherever placed, to converse as though each were located at one of the radio stations. To illustrate the progress made, the demonstration of March 7 1926 might be cited, during which some 20 press representatives in London had two-way conversations with their American confrères.<sup>1</sup> In this test, transmission was effected by wire from New York to the radio transmitter located about 70 m. out on Long Island, where it was automatically relayed to the transatlantic radio link.

*Wire Telephony as an Adjunct to Radio Broadcasting.*—Early in the development of radio broadcasting, it was apparent that the popularity of the programme would be greatly augmented by bringing to the broadcasting station events of public interest such as large orchestral programmes, sporting events and national ceremonies. This virtual extension of the walls of the studio by the use of telephone lines is now a matter of almost daily occurrence, particularly in England and America. As many as 25 or more broadcasting stations are sometimes joined together by a wire network to disseminate the same programme.

*Transmission of Pictures* (see PHOTO-TELEGRAPHY).—Over a long period of years, many schemes were proposed for the electrical transmission of pictures. Although these early systems were in most cases physically operative, none proved practical. To be of commercial value, a system must be at once simple, rapid and accurate. It has remained for developments of late years to meet adequately all of these requirements. In April 1925 the first commercial picture-transmission service, a development of the Bell Telephone engineers, was introduced. This service, embracing the cities of New York, Chicago and San Francisco, made possible the transmission of pictures in either direction between any of these points. The actual sending time of a 5-in. by 7-in. picture is but seven minutes. At the sending end, the picture is required simply in the form of a positive transparency made by the ordinary photographic process, and after transmission it appears as a negative film from which prints can be produced without delay. As it is possible to transmit while the positive transparency is still wet, the total time of transmission is reduced to a minimum.

*Machine Switching Systems.*—A retrospective examination of the manually operated switchboard discloses the fact that the tendency of development has been continuously in the direction of increasing the number and extent of the switching operations that are performed electromechanically, thus decreasing the amount of time and effort required of the operator for the handling of a connection. When a point is reached where the operations performed manually at the central office are entirely eliminated, except in the case of certain special classes of calls, the term "automatic" or "machine switching" is applied to the equipment. In this equipment the subscriber's telephone set is furnished with a finger-wheel or dial having 10 finger holes. These holes are designated by the 10 digits, and for the larger cities also by letters. By inserting a finger in one of the 10 holes, rotating the dial to a stop and then letting it return under the control of a spring, the calling subscriber sends to the central office mechanism a series of from one to 10 electric impulses. In this way the number is given by electrical impulses rather than called, the operation of the dial conveying to the central office mechanism the necessary guiding impulses for setting up the connection desired.

*Main Types.*—There are three principal types of machine switching equipment in extensive use, viz.: the "panel," "step-by-step" and "rotary" types. These names refer to the mechanical design of the devices termed "selectors," which are supplied in the central offices to switch the subscribers' lines into connection with each other. A selector consists of a set of movable terminals which can be connected with any one of a number of sets of fixed terminals and takes the place of the flexible cords, plugs and jacks of the manual switchboard. For

<sup>1</sup>See *Nature*, p. 386 (March 13 1926).

example, in the "panel" type of selector the movable terminals are driven up and down in a straight line over the fixed terminals, which are placed on a flat surface in the form of panels. The step-by-step system was first developed for use in small cities, but redesigned for use in London. The other two systems were developed particularly for use in large cities.

*New Magnetic Materials.*—Among the new magnetic materials developed for telephone purposes, two deserve special mention. One consists of very finely divided iron dust cemented together under extremely high pressure to yield a material of substantially the same density as iron, of only  $\frac{20,000}{100,000}$  the electrical conductivity of iron. The product has nearly the same initial permeability as iron, and yet because of its finely divided ingredients, and the consequent microscopic free poles distributed throughout it, the material possesses practically no residual magnetism even after exposure to strong fields. The second new magnetic material, also a development of the Bell system engineers, has been called *permalloy*. It is so sensitive to magnetising influences that it is completely saturated in the earth's field and is making possible important advances in various branches of the communication art. For example, in co-operation with the Western Union Telegraph Co., a submarine telegraph cable loaded with permalloy has been laid between New York and the Azores, the message capacity being about four times that of the standard type of cable. The permalloy in tape form is wound as a cylindrical covering around the copper conductor, and, because of its very high initial permeability at low magnetising field strengths, causes a more rapid building up of current at the receiving end, which in turn results in increased speed of sending. Permalloy is also being employed in the magnetic circuits of many telephones and telegraph relays, telephone transformers and receivers.

*The Use of the Telephone.*—Coincidental with these technical advances in the telephone art, there has been a notable increase since 1910 in the use of the telephone throughout the civilised world. The accompanying table shows the number of telephones in the principal countries and continents at Jan. 1 1910 and at Jan. 1 1925, the latest date for which comparative data are available. The number of telephones per 100 people, which is also shown in the table, affords a means of comparing the telephone development of areas differing widely in total population and in total number of telephones. It will be noted that the aggregate number of telephones in service throughout the world increased from about 10,400,000 to over 26,000,000 in the 15 years under consideration. Table I. shows that, at the end of this period, 62% of all the telephones in the world were in the United States, 26% were in Europe and the remaining 12% were scattered among all other countries.

Great Britain and Northern Ireland had, at Jan. 1 1925, somewhat less than 5% of the world's total telephones, Germany had slightly over 9% and France about 2.5% of the total. There was, at that date, one telephone for every 7 people in the United States, one for every 36 people in Great Britain and Northern Ireland, one for every 26 people in Germany and one for every 58 people in France. Sweden had one telephone for every 14 people, Norway one for every 16 people and Denmark one for every 11 people. The Scandinavians also rank high among Europeans in respect to the use of the telephone. During a recent year there were 131 telephone conversations *per capita* in Denmark, 113 in Norway, 106 in Sweden, 23 in Great Britain and Northern Ireland, 30 in Germany and 20 in France. The corresponding annual figure for the United States was 191 telephone conversations *per capita*.

*The Telephone and the War.*—The increment between 1910 and 1925 in the world's total telephones does not, of course, represent an even growth throughout the period. The normal rate of increase was decidedly retarded in the principal telephone-using countries during the World War. The difficulty and high cost of securing and shipping telephone supplies was felt throughout the world. In the belligerent countries these conditions were intensified by the necessity of giving priority to war requirements and the telephone systems were further handicapped

by the depletion of their working forces to supply communication technicians for the military and naval forces.

For example, about 13,000 out of the 20,000 men in the engineering department of the British Post Office joined the army. After the United States entered the War, nearly 25,000 employees of the Bell system joined the war service of the Government. Of this number 233 were women telephone operators who were recruited and sent overseas; and hundreds of others were in training for this service at the time of the Armistice. An enormous amount of telephone construction was also carried out to meet the wartime need for extra telephone service in Washington and at army posts, camps and cantonments, aviation fields and naval and coastguard stations.

Experience with the telephone in the World War practically revolutionised modern military practice in the maintenance of communications (see *SIGNALLING, ARMY*). The Signal Corps of the U.S. Army, for example, constructed during the War 1,990 m. of permanent pole line with 28,000 m. of wire, erected 3,230 m. of wire on French poles, and installed approximately 40,000 m. of combat lines. American military telephone exchanges on permanent lines in France numbered 273, and those in the advance section 123, besides small temporary field installations. About 1,600,000 long-distance telephone calls were handled by the Signal Corps, in addition to local telephone calls estimated at 47,000,000.

*Post-War Development.*—After the War, the accumulated demand for telephone service in various countries was sufficient to accelerate telephone expansion to the maximum rate permitted by the amount of telephone apparatus which could be made available. In Japan, however, a further setback was experienced as a result of the disastrous earthquake of Sept. 1923, which put out of service upwards of 70,000 telephones, or more than one-eighth of all the telephones in the empire. In the re-establishment of service in the devastated area the opportunity is being taken to introduce "automatic" or "machine-switching" systems in place of the manual equipment formerly used. A like change is gradually being made in many of the large urban telephone systems throughout the world. By the end of 1925 the number of automatic or machine-switching telephones in the United States exceeded 1,650,000.

*Administrative Changes.*—Some important changes in telephone administration have taken place in Europe since 1910. In Great Britain, on Dec. 31 1911, the British Post Office took over the entire telephone system of the National Telephone Company. All public telephone service in Great Britain and Northern Ireland is now rendered by the Post Office, except at Hull and on the islands of Guernsey and Jersey, where the telephone systems are operated by the local authorities. Upon the establishment of the Irish Free State, the British Post Office transferred to the Free State Govt. its telephone system in Southern Ireland. In 1916 the Netherlands Govt. acquired the 19 exchanges of the Netherlands Bell Telephone Company. Other local systems owned by private companies or by municipalities have been taken over by the Govt. from time to time; but the local telephone service in the larger Dutch cities is still under municipal operation. The interurban lines are owned and operated by the Netherlands Government. The Swedish Govt. in 1918 purchased the telephone system of the Stockholm Telephone Company. On the other hand, a tendency has been manifest in Europe, since the War, toward the extension of private enterprise in preference to government ownership in telephone administration. The Spanish Govt. has transferred its publicly owned telephone system to a private company, which has been granted a concession for the development of a nation-wide telephone network. Local telephone systems formerly operated by the Govt. of Italy have been ceded to private concerns under concessions covering limited territorial zones. The Polish Govt. has transferred its telephone properties in a number of cities to a corporation in which it has only a minority interest. Elsewhere, notably in Germany, official action has been taken looking to the establishment of a form of administration for the national communication services which shall approximate as closely as practicable the corporate organisation commonly employed by private enterprise. At Jan. 1 1925, approximately 71% of the world's telephones were privately owned, and the remaining 29% under public ownership.

*International Telephone Communication.*—The improvement of international telephone communication has received much attention during the period under consideration. The Bell system in the United States has been connected by submarine cable with the telephone system of Cuba and its long-distance lines afford access to many points in Canada. In Europe, although the distances between the principal cities are less than those covered by circuits in everyday commercial use in the United States, long-distance telephony has encountered obstacles. Differences of language, of equipment and of operating practices

have exerted a restrictive influence on long-distance communication, particularly across international boundaries. European telephone authorities have, however, taken cognisance of this situation. An international conference was held at Paris in March 1923, to organise a "*Comité Technique Préliminaire pour la téléphonie à grande distance en Europe*" in which Belgium, France, Great Britain, Italy, Spain and Switzerland were represented. Various technical proposals were adopted looking to the betterment of long-distance telephony in Europe. A permanent secretariat and a continuing advisory international technical committee were set up. At subsequent technical conferences additional countries have been represented and further progress has been made in the study of the technical problems involved. Greater difficulties are presented, however, by the question as to what, if any, form of international organisation should be entrusted with the administration or supervision of international telephone circuits.

TABLE I. *Telephone Development of the World, Jan. 1 1910 and 1925*  
(Some of the figures are necessarily partly estimated)

|                                  | Jan. 1 1910          |                               | Jan. 1 1925          |                               | Increase in the Number of Telephones from Jan. 1 1910 to Jan. 1 1925 |

<sup>1</sup> Exclusive of the Irish Free State.

<sup>2</sup> March 31 1925.

<sup>3</sup> June 30 1924.

<sup>4</sup> Exclusive of 23,800 telephones temporarily out of service as a result of the earthquake.

*Note:* In the case of countries the boundaries of which have undergone change, the figures for each year represent the number of telephones within the boundaries of that year.

England has long been connected with the Continent and with Ireland by submarine telephone cables and the Scandinavian peninsula has enjoyed like facilities for communication with neighbouring European countries (*see TELEPHONY, SUBMARINE*). An event of considerable interest, however, in long-distance telephone extension was the establishment, during 1924, of telephone communication between Spain and Morocco by a cable spanning the Straits of Gibraltar.

TABLE II. *Telephone Wire of the World, as of Jan. 1 1925*  
(Some of the figures are necessarily partly estimated)

|                                  | Miles of telephone wire | Miles of telephone wire per 100 population |

Kingsbury, *The Telephone and Telephone Exchanges* (1915); F. G. C. Baldwin, *The History of the Telephone in the United Kingdom* (1925); A. Lincoln Lavine, *Circuits of Victory* (1921). (W. S. G.)

**TELEPHONY, SUBMARINE.**—Progress in submarine cable telephony has been due partly to improvements in cable design and partly to the introduction of the telephone repeater which has, in turn, reacted on the design of cables.

*Continuous Loading.*—In 1887 Oliver Heaviside, in *The Electrician*, vol. 19, showed that the transmission efficiency of a telephone circuit could be improved by artificially increasing the inductance of the circuit. So far as submarine cables are concerned this had been effected by "continuous loading" up to the year 1910. "continuous" or "krarup" loading is effected by winding wire or tape of magnetic material, generally iron, in a close spiral on the conductors of the circuit. Unfortunately in addition to increasing the inductance of the circuit the effective resistance to alternating currents is also increased as well as the

mutual capacity between the conductors. In practice this has hitherto imposed a limit of approximately 20 millihenries per nautical mile as the maximum inductance which can be obtained in a continuously loaded cable. In order to obtain a greater increase in inductance "coil loading" has therefore been resorted to. In 1910 a coil loaded cable was manufactured and laid by Messrs. Siemens Bros. & Co. for the British Post Office between Abbot's Cliff near Dover and Cape Gris Nez in France. Details of the cable are given in the table on page 752. The loading coils are spaced at intervals of one nautical mile ("naut").

*Efficiency of Circuit.*—The efficiency of a telephone circuit is measured by the ratio of the current received to the current sent into the circuit. This ratio is expressed by the formula  $e^{-\beta l}$  where  $e$  is the base of the Napierian system of logarithms,  $\beta$  is the attenuation constant per unit length of circuit and  $l$  is the length of the circuit. The naut will be taken as the unit length for the purpose of this article. For the cable referred to above the value of  $\beta$  for the cable unloaded is 0.0524 and for the loaded cable 0.0166. Therefore for the same efficiency the loaded cable could be rather more than three times the length of the unloaded cable. The value of  $\beta$  depends upon the electrical constants of the circuit. For a coil loaded cable the natural inductance is usually small compared with the inductance added by the loading coil and may therefore be ignored. The following approximate

formula may then be used  $\beta = \frac{R + \left(\frac{R_1}{L_1} + \frac{G}{C}\right)L}{2} \sqrt{\frac{C}{L}}$

where  $R$  is the loop resistance of the circuit in ohms,  $C$  the mutual capacity between the conductors of the circuit in farads,  $L$  the inductance in henries and  $G$  the leakance in mhos, all per unit length of circuit.  $R_1$  and  $L_1$  are the effective resistance, and the inductance of the loading coils respectively. All these values are to be taken at the particular alternating current frequency under consideration. In the formula given the two quantities  $R_1/L_1$  and  $G/C$  represent properties of the loading coils and of the dielectric respectively. In the Anglo-French cable already mentioned, the value of the former is 60 and of the latter roughly 120 at 1,000 cycles per second. In the next cable laid, the Anglo-Belgian cable, the value for  $G/C$  was reduced to 12, at 800 periods per sec., by using balata in place of gutta percha. As regards the quantity  $R_1/L_1$  the value has been reduced to 40.

In addition to the coil loaded cables shown in the table two coil loaded cables have been laid from Dungeness in England to Audresselles in France, two from Dover to Sangatte, and one from St. Margaret's Bay to La Panne, Belgium. In the Abbot's Cliff-Gris Nez cable only the two physical circuits are loaded but in all subsequent cables additional coils have been introduced to enable a third loaded circuit to be provided by superposing. The addition of these coils slightly increases the attenuation constant for the physical circuits, on account of the additional resistance introduced by the superposed circuit coils. In the year following the laying of the Abbot's Cliff-Gris Nez coil loaded cable the French Govt. laid between the same points a continuously loaded cable with gutta percha insulation, details of which appear in the table.

The loading of the physical circuits automatically loads the superposed circuits. A fourth circuit operated as an earthed circuit can be worked over all four wires on which the loop superposed circuit is formed provided that the electrical balance of the conductors is such as to prevent undue crosstalk, and that interference from earth currents is negligible. This system has been worked over the Vancouver-Victoria, B.C., cable manufactured by Messrs. W. T. Henleys Telegraph Works Co.

*Telephone Repeater.*—The growing demand for circuits for international communication is leading to the adoption of cables with more numerous conductors. This is rendered practicable by the developments which have taken place in the telephone repeater consequent upon the introduction of the three electrode thermionic valve. The use of the telephone repeater, which amplifies the speech currents, enables smaller conductors to be used and an increased number of circuits can thus be provided

in a given size of cable. An example of such a cable is the Leba-Tenkitten cable across the Bay of Danzig. This cable contains 12 telephone wires laid up in three groups of four wires (quads) and three telegraph wires all paper insulated. It is provided with two lead sheaths, as a precaution against the penetration of water. In order to assist the lead sheath in supporting the external pressure to which the cable is subjected a spiral of steel wire is placed between the cable core and the lead sheaths. Further, the armouring, instead of the usual cylindrical wires, consists of wires drawn roughly Z shape so as to interlock and form a practically incompressible tube. The ordinary jute serving over all completes the cable. The direct current resistance of the telephone conductors per naut loop is 20.9 ohms for the physical circuits and 10.45 ohms for the phantom circuits. The increase of resistance with frequency due to the loading is indicated below, where  $\omega = 2\pi \times$  the frequency. The testing current was 2 ma.

|--------------------|------------------|------------------|------------------|
|                    | $\omega = 3,000$ | $\omega = 5,000$ | $\omega = 7,000$ |
| Physical circuit   | 0.445 ohms       | 1.17 ohms        | 2.17 ohms        |
| Superposed circuit | 0.241 " "        | 0.538 " "        | 0.965 " "        |

The rise in resistance as the frequency increases involves an increase in attenuation of the higher speech frequencies. Frequencies up to 2,000 per sec. corresponding to a value of  $\omega = 12,400$  approximately, must be transmitted without serious loss if good commercial speech is to be obtained. Special attention is therefore paid to the resistance-frequency characteristics of cables with a view to the efficient transmission of the higher frequencies. In 1924 the first continuously loaded paper core cable between England and the Continent was laid between Aldeburgh, Suffolk, and Domburg, Holland, for the Anglo-Dutch service.

This cable contains 16 wires (four quads) providing eight physical telephone circuits and four superposed circuits. Each conductor consists of a center wire 0.076 in. (1.93 mm.) in diameter surrounded by three copper strips each 0.010 in. (0.254 mm.) thick; weight 165 lb. per naut. Each conductor is wound with two layers of 0.008 in. (0.203 mm.) diameter iron wire; weight 87 lb. per naut. The loaded conductor is wrapped with paper to a diameter of 0.188 in. (4.77 mm.). Two lead sheaths are provided, the external diameter of the outer lead sheath being 1.52 in. (37.6 mm.). The armouring consists of 24 cylindrical wires 0.232 in. (5.9 mm.) diameter. The overall diameter of the cable is 2.42 in. (61.5 mm.). No steel spiral is provided between the core and the lead sheath, as the water in which the cable lies is comparatively shallow. The length of the cable is 82.242 nauts. It terminates in a telephone repeater station at Aldeburgh and is extended on the Dutch side by a continuously loaded underground cable to a repeater station at Middelburg. It provides circuits between London and Rotterdam, Amsterdam and The Hague.

In the operation of the two-wire telephone repeater the circuit on each side of the repeater station is balanced by a network having the same impedance as the circuit over a range of frequencies corresponding with the range of speech frequencies to be transmitted. Unless the electrical constants of the circuit are uniformly distributed the curve connecting circuit impedance with frequency will not be smooth and an accurate balance becomes impracticable. The repeater could not then be worked at its highest efficiency. In the Anglo-Dutch cable the impedance frequency curve is so smooth that so far as the cable is concerned the highest amplification which the repeater is capable of giving could be used. Other factors not connected with the submarine cable limit the amplification actually obtained. A second similar cable will shortly be laid between the same points by the Dutch Government. The success of the Anglo-Dutch cable has led to the decision to adopt a similar type of cable for the Anglo-Belgian and Anglo-French cables in each of which 28 conductors will be provided in seven quads giving 14 physical circuits and seven superposed circuits.

The make up of the cables will be as follows:—Conductor, solid wire 0.08 in. (2.03 mm.) diameter; weight 118 lb. per naut. Loading is one wrapping of iron wire 0.008 in. (0.203 mm.)

Examples of Loaded Cables for Submarine Telephony

| Cable                                      | Date Laid             | Length in nauts | No. of Conductors    | Weight lb. per naut | Conductor Diameter mm.                                                                      | No. of layers and Diameter of Loading Wire mm.   | Dielectric                                 |                       | Electrical Constants per naut loop |                              |                | Characteristic Impedance                        | Attenuation constant      | Reference                                                  |

<sup>1</sup> Measurements made at 1,000 P.P.S.<sup>2</sup> Measurements made at 800 P.P.S.

diameter; weight 34 lb. per naut. Each conductor will be wrapped with paper to a diameter of 0.156 in. (3.96 mm.). There will be two lead sheaths each 0.085 in. (2.16 mm.) thick; external diameter over the outer lead sheath will be 1.66 in. (42 mm.); armouring 26 wires 0.232 in. (5.9 mm.); weight of complete cable per naut will be 26.5 tons; overall diameter 2.58 in. (65.5 mm.).

The approximate electrical constants are given in the following table:—

To preserve uniformity of electrical constants throughout the section of line between Canterbury in England and La Panne in Belgium and between Canterbury and Boulogne in France, at each of which places repeater stations will be provided, a similar type of cable core will be used for the underground cable between the repeater stations and the landing point of the submarine cables. The total length of the Belgian cable will be 68½ nauts of which 50 nauts is the length of the submarine section. The total length of the French cable will be 47.3 nauts of which the submarine section is 23½ nauts.

These two submarine cables will be extended to London by an underground cable. The Belgian cable will also be extended by underground cable in Belgium. The French cable will be extended by underground cable to Paris with telephone repeaters at Poix and Boulogne.

A different type of cable was laid in 1921 between Key West and Havana. The depth of the sea for part of the route is about 1,000 fathoms (1,830 metres). A special type of cable was designed owing to the great water pressure to which the cable would be subjected. Three single core continuously loaded cables were laid, the insulating material being a special mixture of gutta percha. A cylindrical return conductor was provided surrounding the gutta percha. This was made up as follows:—First a copper tape 1 in. (2.54 cm.) wide and 0.004 in. (0.1 mm.) thick was applied directly upon the core with the turns overlapping; over this were laid two copper tapes each 0.625 in. (1.59 cm.) wide and 0.0222 in. (0.56 mm.) thick laid with edges touching. The armouring varies according to the depth. Each cable provides a telephone channel, a direct current duplex and a carrier current duplex telegraph circuit.

*Use of Permalloy.*—The future development of the continuously loaded cable depends on finding a magnetic material with a higher permeability for the loading wire (or tape), to increase the inductance, and having also a high electrical resistance to reduce the losses due to eddy currents in the iron, the effect of which is to increase the effective resistance of the circuit. A material called "permalloy," an alloy of nickel and iron, has been used for loading the New York-Azores telegraph cable which represents a step in the direction mentioned (see *The Journal of the A.I.E.E.*, Aug. 1925).

The continuously loaded cable appears very suitable for use in conjunction with telephone repeaters as should repairs, involving an increase in length at the point of repair, become necessary, the uniformity of the cable would be preserved, whereas with a coil loaded cable, in similar circumstances, an

irregularity would be introduced which would affect the operation of the repeaters. The accompanying table of cables is intended to give examples of various types of cable and not to offer a complete list of modern telephone cables.

**TELEPHOTOGRAPHY:** see PHOTOTELEGRAPHY.

**TELESCOPE** (see 26.557).—For the purpose of outlining the treatment adopted in this survey of progress since 1910 astronomical telescopes may be classified as follows:—

I. Reflectors. II. Refractors: (a) visual, (b) photographic; (1) moderate fields, (2) wide fields.

All of these forms belong properly under the head of telescopes except the last one (II. b 2), which belongs more properly to such a subject as the camera or photography.

*Comparative Merits.*—The respective merits of the several kinds of telescopes for astronomical observations of one kind or another are determined by both theoretical and practical considerations. The theoretical considerations relate to colour performance and field, and are fundamental. The reflector has no chromatic aberration whatever but has only a limited field of critical definition, while a good refractor has a larger field but is never entirely free from secondary spectrum. Other considerations of rather a fundamental nature relate to the superior light efficiency of the reflector at large aperture and the relatively greater latitude allowable in the selection of the glass from which they are made. These important factors will always weigh against each other very considerably as they do now and have done in the past.

Practical considerations relate to such matters as attainable perfection of surface, sensitiveness of the telescope to temperature changes, convenience of handling and a multitude of things whose incidence on telescopic performance will vary as improvements in technical processes bring one or another of them under control. From the maker's point of view a mirror has the important advantage that it has only a single surface to be figured, while a lens has at least four, but this is more or less offset by the necessity of working the one surface to an extremely high degree of accuracy. There seems at present to be substantial ground for the hope that the provision of mirror material of low expansion coefficient and good working quality will contribute materially to the attainment of accurate surface and that the disadvantage just mentioned will be lessened.

The distinction between the two types of refractors, visual and photographic, relates primarily to colour correction, the one being adapted to the region of the spectrum to which the eye is most sensitive, and the other to the blue-violet region. There is, however, a secondary consideration, which is, in effect, equally important, namely, that the eye can utilise only a small telescopic field, while the photographic plate can take full advantage of a large one, so that lenses intended for photography receive careful treatment for field (see PHOTOGRAPHY).

## I. REFLECTORS

The trend of telescope building since 1910 has been decidedly toward the construction of reflectors. The movement in this direction had set in at the opening of the century, and had resulted by 1910 in the construction of the 5-ft. reflector of the Mount Wilson Observatory. Since then the 100-in. Mount Wilson and the 72-in. Victoria reflectors have been built (see plate), while at least two of 60-in. aperture are reported to be nearing completion.

*The Mount Wilson Telescope.*—The diameter of the mirror is 100.4 in. (255 cm.), the focal length 42.3 ft. (12.89 metres). The tube of the telescope is swung in a split polar axis, as described under "B" in the résumé of types of equatorial mounting in vol. 26, p. 565, the cross pivots on which the tube rotates serving as the declination axis. The great weight of the telescope (100 tons) is carried by large drums situated at the upper and lower ends of the polar axis, which float in troughs of mercury, while the actual direction of the axis is determined by self-aligning spherical bearings near its two extremities. The telescope can be used either in the Newtonian or Cassegrain form, separate terminal sections of the tube being provided as carriers for the auxiliary mirrors of each. These carriers, or "cages" as they are called, are very massive, and are removed and exchanged with the aid of an electric crane (see the upper left background of plate). When it is necessary to remove the mirror for silvering, which is about twice a year, it is lowered by means of a large hydraulic jack into a laboratory just beneath the floor. The two large tubes lying parallel to the telescope contain weights that can be moved longitudinally to perfect the balance. The hour and declination circles are read through the small telescopes seen on the desk. The instrument is provided with quick and slow motion devices operated electrically, and essentially all movements of it and of the dome are accomplished by motors under independent control by the observer at the eye end and the assistant at the desk. Forty motors and 14 m. of wire are used in the dome. The mirror is supported by a counterpoise system similar to that of the 60-in. telescope (see 26, 569), and there is provision for making the same optical dispositions as are described in conjunction with that telescope. In order to minimise the effect on the mirror of changes in the temperature of the air, it is surrounded by an insulating sheath of cork-board. Means were originally provided for keeping the mirror cell jacketed with brine, which was automatically held at a constant temperature, but they were eventually discarded and reliance was placed on the cork insulation as well as on the protective covering of the dome.

Access to the Newtonian focus, at the upper end of the tube, is by means of an adjustable platform, which is swung in the dome opening and is reached by means of the ladder in the right foreground (see plate). A ring section of the floor, extending from the dome inward to the circular rail, forming part of the dome and rotating with it serves to stiffen the dome and contributes to the smoothness of its operation. The dome and walls are double sheathed for the purpose of reducing the diurnal range of the interior temperature.

*The Victoria Telescope.*—The diameter of the mirror is 72.5 in. (184.15 cm.), the focal length 30.1 ft. (9.180 metres). The mounting is of the so-called British form, designated as Type A (26-565). Critical features of this telescope, other than those apparent in the illustration, are the polar axis bearings and the construction of the tube. The polar axis rotates in ball bearings of large size, unrelieved by supporting or flotation devices. This departure from usual practice in the construction of large telescopes has proved very successful. The lattice-work part of the tube is built as a unit, without removable end pieces such as those of the Mount Wilson telescope, provision being made for the direct interchange of the Cassegrain mirror, the Newtonian mirror and the focal plane apparatus without the removal of a terminal section of the tube. The telescope is electrically operated.

*Comparisons of Three Large Reflecting Telescopes.*—The two telescopes just described and the earlier 60-in. reflector at Mount Wilson possess a high degree of excellence. Incomparable photographs of the Moon, the nebulae and other objects are the product of the Mount Wilson instruments, while the power of the Victoria telescope for spectroscopic observation has fulfilled the most sanguine expectations of its projector. But these instruments suggest a comparative study of different types of telescopes. Each of them differs in size and in pattern from the others and from the proof by trial of the many departures in design is to be derived information essential to the determination of the steps by which further progress is likely to be made.

The split or yoke form of polar axis used in the 100-in. telescope has the advantage that the very heavy tube is swung between pivots and does not overhang the polar axis. This construction makes for stability and centres the telescopes in the dome, advantages purchased at the cost of access to a con-

siderable area of the sky surrounding the North Pole. The range of this telescope is still further reduced by interference of the large float at the upper end of the polar axis. In adopting this form of mounting the designers were no doubt influenced by the circumstance that the Mount Wilson observatory already possessed a powerful reflector capable of covering the entire sky, so that in the region inaccessible to the proposed telescope the loss would be merely that of the marginal efficiency of the larger over the smaller instrument. The excellent mechanical performance of the Victoria telescope suggests that the limit of size for a mounting of its type has not been closely approached, and it seems likely that the design might be used for a very much larger instrument. The use of ball bearings in the polar axis of the Victoria telescope has proved so successful that it is doubtful whether a return will be made to the system of counterweighted rolls, or to the rather cumbersome mercury floats and tanks. Neither of the latter devices provides the ease of motion that is secured in the Victoria telescope, nor does it appear to be superior in stabilising the position of the axis. With respect to the mechanical performance of the telescope, Prof. Plaskett writes: "I can only repeat what I have said before, that it is a joy to operate and use the instrument."

Fortunately, for the purpose of comparative study two of these great instruments are located at the same observatory. The 60 and 100-in. telescopes have now been in operation at Mount Wilson since 1920 under identical atmospheric conditions and in the hands of the same observers. The following comments are excerpted from a personal letter written by Director W. S. Adams of the Mount Wilson Observatory in reply to an enquiry relative to the performance of these two instruments:—

In ease of control the 100-in. telescope is considerably superior to the 60-in., and the dome and shutter are vastly better. We could not improve upon the dome and shutter mechanism if we had them to do over again. One feature of the controls worth noting is the automatic speed change for right ascension and declination slow motions: this has proved almost invaluable in making settings around an instrument where the distances are so great.

If the instrument were to be built at present I certainly think we should do away with mercury flotation. The northern float cuts off an important area of the sky from observation, and the mercury tanks give us considerable trouble with changes of temperature. Large roller and ball bearings have developed greatly since the 100-in. telescope was designed, and I am sure they would now serve this purpose excellently. However, the driving of the 100-in. under normal conditions is very fine. Probably our flotation system could have been made much better if we could have used a greater volume of mercury. It was built during the War, when mercury was almost unprocureable, and we got along with the irreducible minimum.

We have not used the cooling system around the 100-in. mirror since the first few months, and about four years ago we took out the circulating pipes. The insulating cover has proved very efficient, and our automatic temperature records rarely show a range of over 20° C. in the air surrounding the mirror. This insulation is about the most important single feature of the entire telescope, and I think it could be improved upon in future large instruments.

Our experience has shown that the number of nights when we get full benefit of the 100-in. over the 60-in. is surprisingly large. With seeing of 2 or better on a scale of 5 we regularly give exposure times with the spectrograph at the Cassegrain focus one-third as long, and it is only when the seeing is below 2 that the proportion becomes much worse. In very bad seeing, however, the 100-in. is nearly hopeless.

In general, the performance of the 100-in. telescope depends very largely upon the figure of the mirror when the seeing is 2 or better. This is very susceptible to changes of temperature, and a general rise or fall of the mean temperatures of successive nights gives rise to astigmatism which is sometimes very persistent. Our worst figure comes in winter after a cold wave, or a storm after which the temperature begins to rise rapidly. In summer, with settled weather, the figure is usually good with the occasional exception of the first hour or two after dark, when the edges are distorted.

Dr. Hubble has given me the following table of the mean diameters of the faintest stars registered on plates with full aperture and exposures of 30 minutes:—

Seeing 2 to 3 on a scale of 5.

| Figure of Mirror               | Mean Diameters of Smallest Images |
|--------------------------------|-----------------------------------|
| Average . . . . .              | 1.5 in.                           |
| Very good . . . . .            | 1.0 in.                           |
| 2 exceptional plates . . . . . | 0.6 in.                           |

THE MT. WILSON 100-IN. REFLECTING TELESCOPE

THE VICTORIA (British Columbia) 72-INCH REFLECTING TELESCOPE. Specially designed to study star spectra.

In addition to speed and resolution the superiority of the 100-in. is very marked for fine details in nebulosity or other surfaces, and especially for narrow linear features, such as are found in planetaries or network nebulae.

Thus the full advantage of size is secured in the light gathering power of the larger telescope; and the two exceptional plates mentioned by Adams indicate most excellent defining power, for while it is true that the theoretical resolving power for a mirror of that size, 0.05 in. is not reached, it is probably more closely approached by this than by any other large mirror in use. Further, the diameters were measured on photographs taken with comparatively long exposures, and the images were consequently subject to the usual unsettling influences of photographic observation. It seems safe to state that no existing refractor, nor any that could be made, could compete with the 100-in. telescope in the matter of light delivery. In respect to definition, the superiority probably does not exist. It is perhaps fair to say that on photographs taken with refractors of 30 or 36-in. aperture images of 0.6 in. are to be expected under "good" conditions of observation, and slightly larger ones under average conditions. Furthermore, the figure of a refractor can always be depended upon. With exceptionally steady atmosphere star disks, as seen with the eye through such an instrument as the 36-in. refractor of the Lick Observatory, are reduced approximately to their theoretical size of 0.13.

Thus in the matter either of ultimate or of average definition the refractor still maintains the lead; but if the figure of the Mount Wilson telescope could be stabilised it would, under average conditions of observation, compare favourably in respect to definition with the best refractors.

*Causes of Instability of Figure.*—The principal factor contributing to instability of figure is ununiformity of thermal distribution through the material of the mirror, resulting from ordinary changes in temperature of the surrounding air. It has long been realised that this effect might be reduced through the employment of a mirror material of low expansion coefficient and "Pyrex" mirrors of moderate size, which are in use at Mount Wilson, are said to suffer only about  $\frac{1}{10}$  the focal disturbance of those of glass.

*Importance of Fused Quartz.*—Fused quartz, the thermal expansion of which is almost negligible, has been suggested as a material for telescope mirrors, in fact experiments looking toward the production of that material in disks sufficiently large for the purpose were undertaken by Prof. Elihu Thomson in the opening years of the century. At that time the material was rather a curiosity, and was obtainable only in small pieces. In the hands of Thomson the extremely difficult technique of quartz fusing has been sufficiently mastered to permit the production of disks approximately a foot (30 cm.) in diameter. A mirror of this material would be immune from the disturbing effects of temperature and would retain excellence of surface under essentially all conditions of observation. Dr. Thomson, in some very illuminating letters relating to fused quartz, expresses the opinion that with proper mechanical facilities, disks of a quality suitable for mirrors can be produced in whatever size may be desired. With respect to the working qualities of the material he says:—

I find the work of fused quartz for optical surfaces is peculiarly satisfying in that its freedom from expansion makes it unnecessary to look after the temperature of the workroom or take precautions as to its unequal heating. The grinding proceeds with the utmost satisfaction, without danger of scratches, which is always a trouble with glass, and a very fine surface just before polishing is attainable with comparative ease.

Since the property of fused quartz, which insures stability of surface, also facilitates the shaping of the mirror, the use of this material may be expected to result not only in a more quiescent surface but also in mirrors of greater perfection. On the production of fused quartz, or something equivalent to it, more than on anything else, depends the full utilisation of the advantages of the reflecting form of telescope.

*Theoretical Considerations.*—Two attempts of a theoretical nature have been made to overcome the field limitations of instruments of this class. Where the optical system consists of a single

mirror the shape of the surface is uniquely determined as that of a paraboloid of revolution. In the Cassegrain and Gregorian forms there are, however, two reflecting surfaces, and it is possible, within limits, to balance departure from the paraboloidal form of the primary by reciprocal alterations in the surface of the secondary mirror. The problem whether it is possible to do this to the advantage of the field has been attacked by Schwarzschild and by Sampson. The investigation of the former is, in the present state of the art of glass working, hardly more than of theoretical interest. Sampson, besides modifying the reflecting surfaces, brings into the system a number of glass lenses, all of the same material, which without introducing sensible chromatic aberration provide a field comparable with that of a good refractor. The suggestion seems promising for the future, but no instrument of the proposed type seems as yet to have been constructed.

## II. REFRACTORS

The production of refractors has not been entirely neglected, and much more would undoubtedly have been accomplished in this direction but for the War, which proved especially disturbing to the optical industry (*see* OPTICAL GLASS). The instruments include a few intended for general observational purposes, but a very significant departure has been made in the direction of photographic telescopes. Among the pioneers in large instruments of this class is a 30-in. (76 cm.) Thaw telescope of the Allegheny Observatory, which has proved extremely efficient in the determination of stellar parallax, in the study of star clusters, and in other investigations which require, or derive advantage from, a larger field than is provided by a reflecting telescope. As a result, possibly, of the success of that instrument the construction of a number of others has been undertaken, notably one of 24-in. (61 cm.) aperture for the South African station of the Yale Observatory, and one of 41-in. (104 cm.) aperture and 35 ft. (10.66 metres) focal length (which will be larger than any refractor now in existence) for the Nikolayev Observatory in south Russia. A 24-in. (61 cm.) instrument of 35 ft. (10.66 metres) focus is under construction for the National Observatory near Santiago, Chile. At Johannesburg there has recently been installed a 26-in. (66 cm.) visually corrected telescope, and one of approximately the same aperture is being built for the South African station of the Detroit Observatory.

## LENS DESIGN

The most noteworthy advances in design have been made in relation to lenses of wide field. A number of new lenses have appeared since the War, the stimulus for this development being provided perhaps by the necessities of aeroplane photography. A lens calculated by F. E. Ross for work of that nature has, on modification for astronomical requirements, proved very successful, notably in the extremely exacting observations made during a solar eclipse for the measurement of the gravitational displacement of light. Among the excellent wide-angle wide-aperture lenses constructed in recent years are the 16-in. lens of the Arequipa station of the Harvard Observatory, and the 10-in. at Mount Wilson, both of the Cooke type, while a number of lenses of the Petzval type are in successful operation in Europe and America.

## IMPROVEMENTS IN MATERIAL AND METHODS OF MANUFACTURE

Certain glasses having optical characteristics that would lend themselves to the reduction of secondary spectrum are barred from use by their chemical instability, or by the possession of detrimental physical properties. It seems improbable that any marked departure from the existing run of optical properties (refractive index, etc.) will be effected without a serious sacrifice of durability. However, an important English firm of glass makers is reported to have improved the transparency of optical flint glass, and to have produced successfully a large disk of dense barium crown (*see* OPTICAL GLASS). The refractive characteristics of glass of the latter type make it especially valuable for the suppression of coma, and its availability holds out hope for marked improvement in the optical performance of refractors. Deterioration of the surface of glass under the action of

air and the weather is occasionally noticed in the most valuable telescopic objectives. Experiments directed toward the prevention of such impairment have been undertaken by the British Scientific Instrument Research Assn., apparently with some prospect of success.

*Testing of Lenses.*—Among improvements in facilities for testing of lenses may be noted an adaptation to this purpose, by Twyman, of the Michelson interferometer. The instrument is applicable to the testing of small lenses, rather than of large ones, the present limit of aperture being about  $5\frac{1}{2}$ -in., but within its range tests of extreme accuracy can quickly and conveniently be made. Lenses and mirrors of large size are still tested by long-established methods.

*The Telescope-Interferometer.*—The outstanding achievement of observational astronomy during the opening quarter of the present century was the measurement of the diameters of giant stars with interference apparatus attached to the 100-in. Mount Wilson telescope.

The writer is greatly indebted for information to Messrs. W. S. Adams and F. G. Pease of Mount Wilson, J. S. Plaskett of Victoria, B.C., Elihu Thomson of Lynn, Mass., and F. Twyman of London.

**TELEVISION.**—Although, strictly speaking, the word television might be held to cover any means of seeing distant objects, such as ordinary telescopic vision, the term is in practice restricted to the seeing of distant objects through the intermediary of long electromagnetic waves, passing either through empty space or along wires. Since such waves, in their passage over the surface, can follow the curvature of the earth, obstacles which would cut off the direct passage of light from the object to the observer can be disregarded. Again, the long waves are not appreciably scattered by dust or liquid droplets in the atmosphere, and so do not suffer absorption in the sense that ordinary light does. Further, the attenuation of the energy in passing over long distances is less marked than it is with ordinary light, owing to the fact that the long waves do not spread out with spherical symmetry around the source, but tend, on account of the existence of the upper atmospheric ionised layer, to hug the surface of the earth. In addition, the diminution of the energy is of little moment, since modern wireless technique enables us to amplify the signals to any extent desired. Even in cases, then, where light could pass by a direct path from the distant object to the observer, the utilisation of Hertzian waves as a vehicle for the transmission of vision offers certain advantages.

*Mode of Transmission.*—For television we must have a transmitting apparatus, by means of which the light from the object is transformed into electric impulses. These electric impulses must then be amplified and made to modulate a carrier wave, as in the case of wireless telephony. At the receiving end the modulated wave must be transformed into current impulses, which can then be used to modify or steer a light source so as to make it imitate in intensity the light falling on the transmitting system.

It is clear that in the transmitter any light-sensitive cell such as is used in the telegraphic transmission of photographs, *i.e.*, a selenium cell (*see* SELENIUM) or a photoelectric cell, can be used to convert a light of fluctuating intensity into a corre-

sponding current impulse. The amplification of the current and the modulation of the carrier wave can be carried out with the help of electronic relay tubes ("valves") by the ordinary method of wireless telephony. The invention of these relays is, of course, one of the things that make television a practical project. At the receiving end the modulated wave produces current impulses which can be made to govern the intensity of a light beam in various ways: for example, the deflection of the string in a galvanometer of Einthoven type might move a very light and small disk so as partly to obscure or release a light beam, or the amplified current might be passed through a glow discharge lamp of the neon type, which responds without appreciable lag. In this way fluctuations of light falling on the light sensitive transmitting cell could be made to reproduce themselves at the receiving end, by the intermediacy of Hertzian waves.

An imaginable way of adapting these devices to send a whole picture in tone would be to imitate the human eye. The eye consists essentially of a large number of light-sensitive cells, each one of which reports to the brain by its own nerve fibre the strength (and colour) of the light falling upon it. An artificial retina would be made up of a large number of photoelectric cells, each one with a corresponding light-governing device at the receiving end. The relative positions of the light-governing devices to one another at the receiving end would, of course, have to correspond to the relative positions of the transmitting cells to one another at the transmitting end. Each cell would then require either its own wire, if wires were used to transmit the impulse, or its own wave-length, if Hertzian waves were used: for this reason, and on account of the extreme minuteness of the cells required, the method is impracticable.

*Possible Methods.*—The only hopeful methods suggested are based upon the persistence of vision, and demand the use of one cell only, on which falls in sequence light gathered from different parts of the picture to be transmitted. At a given instant light from a given small patch of the picture is focused on to the light sensitive cell, and the picture is "explored" or "scanned," *i.e.*, there is some moving element in the focusing system which selects successively and systematically different parts of the picture until the whole has been covered. At any one instant the strength of the governed beam at the receiving end—the recording beam—corresponds to the intensity of light proceeding from a small patch of the picture at the transmitting end. If now the recording beam can be moved in exact synchronism with the scanning beam at the transmitting end, so that not only the intensities but also the positions of the two beams exactly correspond, the picture will be traced out at the receiving end. If the whole picture can be scanned and transmitted in something less than a tenth of a second, and the receiving mechanism can respond sufficiently quickly, then, owing to the persistence of vision (28.130) the impression of the initially recorded part of the picture will not have faded for the observer by the time the last parts are being traced out, and the picture will be seen as a whole. If the object to be seen is moving, and pictures be sent in rapid and uninterrupted succession, the scanning beam returning to its initial position and starting again as soon as it has covered the whole picture, then a moving picture will be seen as in the cinematograph.

*Accurate Synchronisation.*—It will be clear that this method demands not only the mechanism already contemplated for modulating the carrier waves so as to produce a correspondence in intensity between the scanning beam and the recording beam, but also a mechanism for producing exact synchronism, in the sense not only that the two beams must move at exactly the same speed, but also that they must always be, at a given instant, at corresponding positions of the picture. If, for example, the picture be scanned in horizontal lines—or, rather, narrow horizontal bands touching each other—then obviously the recording beam must begin a line at exactly the same instant that the scanning beam begins a line, and similar considerations hold if the picture be scanned in any other way, for example in a close spiral.

**Number of Signals Necessary.**—Further, a very large number of separately detectable signals, corresponding each to a small element of the picture, must be sent per second. The ordinary newspaper half-tone reproductions contain some 50 dots to the linear inch, which gives 10,000 dots for a picture two in. square. It must be remembered that, owing to the fact that the image reproduced by a mechanism such as that contemplated above will consist of contiguous patches in tone which may vary in continuous gradation from black to white, whereas the half-tone block consists of isolated dots which are either black or white, the representation will be very much better for a given number of elements in the television picture than in the half-tone block. It is possible that quite good representation would be given with half the number of elements to the linear inch, *i.e.*, only 2,500 to the two in. square. Taking this as a conservative estimate, and 10 pictures per sec. as necessary for the cinematographic representation, also a conservative estimate, it will be seen that 25,000 distinguishable signals per sec. must be obtained.

**Feasibility.**—The carrier wave imposes a limit upon the number that can be sent, for in the modulation a certain number of oscillations are necessary for the building up and dying down of the signals. Taking a wave length of 150 metres, which is about the least at present used in broadcasting, there are 2,000,000 vibrations per sec., and if 50 waves are necessary for effective modulation of one signal, it follows that a limit of some 40,000 signals per sec. is imposed. It may be taken, then, that with the present technique of broadcasting a picture of some two in. square could be produced, if the transmitting and receiving mechanism could deal with the signals at the rate just specified.

**Method Proposed.**—Various patents have been taken out for methods by which the scheme just outlined is to be attained practically. One of the most elaborate is that of the Western Electric Company, described in British Patents Nos. 228961 and 230401. The picture to be transmitted is scanned by a small and very light mirror, which moves so that, if the whole picture be imagined to be covered by a narrow spiral band, successive turns of which touch one another, every point of the spiral is successively thrown on a photoelectric cell. The movement of the mirror is secured by mounting it at the junction of two fine wires crossing one another at right angles in a magnetic field, and passing damped oscillatory discharges, with the required phase of difference, through both wires. The fluctuations of current produced in the cell are amplified and imposed on a carrier wave which at the receiving end controls the speed of the cathode stream in a Braun tube. The tube is provided with a translucent fluorescent screen, and the intensity of the small patch of light produced on this by the cathode stream depends on the velocity of the stream, so that in this way the varying intensity of the light at the transmitting end is reproduced by an apparatus possessing no appreciable inertia. A movement of the cathode stream synchronous with the movement of the light beam at the transmitting end, is produced by a very elaborate device. An evacuated tube—the synchronising tube—contains a photoelectric surface, so arranged that the current from a subsidiary electrode depends upon the position at which a spot of light, of constant intensity, falls on the surface. The scanning mirror, besides exploring the picture, reflects the light from a constant source, which is brought to a focus on the photoelectric surface: as the mirror describes its path this spot of light moves and produces corresponding variations in the current from the synchronising tube. These variations are imposed on the carrier beam: at the transmitting end the cathode beam is moved by two pairs of condenser plates whose planes are set at right angles to one another, the carrier beam varying the potentials of the condensers by suitable devices. The frequency of the synchronising waves being so much less than that of the waves controlling the intensity, the two sets of waves can be imposed on the same carrier beam, and separated at the receiving end by a so-called wave filter. This method is described on account of its ingenuity, but it is doubtful if it is really a practicable one. At any rate, no actual transmission of pictures appears to have been realised by its aid.

**The Baird System.**—At the time of writing, the most promising system appears to be that of Mr. J. L. Baird, who has already succeeded in producing a crude, but convincing, representation of moving objects through the agency of Hertzian waves, and has so achieved a true "vision by wireless." Full details of the method have not yet been made public, as certain devices not disclosed in the patents (B. P. 220604, 230576, 235619, 236978) have apparently been employed, but the experiments have been openly exhibited and the general features of the method disclosed.

The picture is scanned by a system of lenses carried by a revolving

disk. The lenses are arranged in a single turn of a spiral of Archimedes, the angular distance between two lenses being such that as soon as one passes right across the picture the succeeding one begins its passage, while the radial distance, which must be small, determines the closeness of the lines (narrow strips) in which the picture is scanned. The disk is large, so that all the lenses are in the neighbourhood of the edge. Between the picture and the lens disk protrudes the edge of a second disk, pierced by a very large number of close radial slots, and close to this disk is a fixed plate pierced by similar slots, so that as the second disk rotates light is transmitted and shut off in very rapid succession. If a black part of the picture is being scanned, there is, of course, no alternation; for a brighter part of the picture the intensity, but not the period, of the alternations is governed by the luminosity of the part in question and the duration of the alternations of given intensity by the length of the bright strip. The light so broken up falls, after passage through the scanning system, on to a light-sensitive cell of special construction; the alternations of current so produced are amplified and imposed on a carrier wave. At the receiving end the modulated wave is made, by the intermediacy of a suitable relay system, to control the brightness of a glow lamp of the neon type, where, since we are dealing with a luminous gas, and not a luminous solid, the intensity can follow very rapid fluctuations. To reveal the picture a narrow beam from this lamp, falling on a screen, must be moved about in synchronism with the scanning beam at the transmitting end. To move the beam a disk provided with a spiral slot and a disk provided with a radial slot revolve at different speeds in front of one another, the first-named disk having much the higher speed. In this way the spot on the screen is moved in close parallel lines, and, by its changes of intensity, reproduces the picture.

Synchronism is secured with the help of an alternating current generator mounted on the same shaft as the scanning disk. The slow alternations so produced are superimposed on the carrier wave which is used for conveying the variations of intensity which produce the picture. At the receiving end the synchronising wave is separated from the light modulations by a wave filter and is then made to control the speed of the slit and the spiral disk, the speed ratio of which is fixed by a gearing. This mechanism secures synchronism but does not secure that the scanning and tracing beam shall each begin a line together. This last adjustment can be made by hand at the receiving end, and, once it is made, the synchronising mechanism suffices.

In Feb. 1926 Mr. Baird had succeeded, with quite crude apparatus constructed on the lines just laid down, in transmitting recognisable pictures of moving objects such as a living face. The opening and shutting of the mouth, the turning of the head, and such general features are clearly visible, but no finer details appear. It seems, however, to be possible that, with adequate financial support, the method may be developed so as to transmit by wireless waves a clear and detailed moving picture of any brightly illuminated object or scene.

(E. N. DA. C. A.)

**TELPHERAGE** (*see* 7.63).—During the World War the Italian Army made extensive use of the telpher system of transport for fighting in the Alps. It had previously been thought impossible to conduct military operations on the high peaks, but the first days of the War saw whole companies of men clinging hand and foot to the rocky summits.

In road making wonderful results were obtained. Roads were constructed which allowed heavy artillery and motor lorries to reach points where a few months before only a mountain expert would have trod. But the building of roads could not always meet the requirements of troops operating in Alpine districts. The difficulty in such cases was skilfully overcome by means of special mechanical transport. Wire railways or "telphers" were provided, thus economising time, labour and oil, and avoiding congestion of roads. These telphers are a kind of suspension railway. A double metal cable called "bearer" is extended on trestles placed in a straight line at different distances on the sides of the mountain. There are two stations, one at the starting point and the other at the end of the line. In one of these stations there is a motor which works an endless cable (the "drawer") to which are fixed two or more small wagons. The cable turns and draws the wagons supported by the "bearer" cable by means of small wheels which run on it.

Different kinds of telpherage plants were used.

1. *Teleferi*.—These were provisional lines moved by man power and used in the most advanced zones to supply isolated posts or trenches. Their average length was 500 metres and each could carry about 50 quintals a day.

2. *Dismountable Teleferiche*.—These were run by motors and were put up in advanced zones. Their average length was from 1,000 to 2,000 metres, and each could carry from 10 to 20 quintals an hour. They could be dismantled and were portable, and could be installed

even where there were no roads. These lines proved most useful for the transport of supplies in newly occupied positions.

3. *Permanent Teleferiche.*—These were run by motors and were fixed. They were employed at some distance from the lines, and reached a maximum length of 8,000 metres. They could carry about 150 quintals per hour. The telfers covered on an average a rise of 650 metres from the starting-point to that of arrival; but in some cases even 1,500. The trestles were often at very great distances from one another and placed on peaks, while the wagons ran over fearful abysses. In the highest regions the lines often ran at a height of 2,000 to 3,000 metres; a few were installed even at 3,500 metres above sea-level. The telferage lines laid on the Italian front transported in all 33,000,000 quintals, the load of 330,000 railway trucks. The service was under a special central administration with a competent staff drawn from the telfer transport companies (one for each army). There was a department for the supply and testing of material and a depot-school with construction and repairing shops.

**TENNESSEE** (see 26.619), a State of the United States of America. The population in 1920 was 2,337,885 as against 2,184,789 in 1910, an increase of 153,096, or 7% as against 8.1% in the preceding decade. The negro population during 1910-20 decreased numerically from 473,088 to 451,758, and decreased proportionally from 21.7% of the total to 19.3 per cent. The average density of population in 1920 was 56.1 per sq. m.; in 1910 it was 52.4. The urban population (in places of 2,500 inhabitants or more) increased from 20.2% of the total in 1910 to 26.1% in 1920. The following table shows the population and increase per cent of the chief cities from 1910 to 1920:—

| Cities       | 1920    | 1910    | Increase Per cent |
|--------------|---------|---------|-------------------|
| Memphis      | 162,351 | 131,105 | 23.8              |

*Agriculture.*—During the years 1910-25 the interests of the State remained predominantly agricultural, though manufacturing was developing rapidly. The total land area in farms decreased from 20,041,657 ac. in 1910 to 18,310,593 ac. in 1925, while the improved land increased from 10,890,484 to 11,185,302 ac. from 1910 to 1920. The number of farms increased from 246,012 in 1910 to 252,606 in 1925; from 1910 to 1925 the average acreage per farm decreased from 81.5 to 72.5 acres. The average value per farm increased from \$2,490 to \$4,953 from 1910-20, and the value of all farm property increased from \$612,540,836 to \$1,251,964,585. The average value of land per acre in 1920 was \$1.40; in 1910 it was \$1.53. Of the 252,606 farmers in 1925, 217,976 were white and 34,630 were negroes. Of all farmers in 1925, 148,561 were owners; 103,719 tenants; and 326 managers. In 1920 there were 113,374 women farmers. The total value of farm crops in 1919 was \$318,285,307, of which amount \$144,778,157, or 45.5%, represented cereals; the total value in 1909 was \$111,133,210, cereals representing 49.8%. The cereal acreage in 1919 was 4,186,373 acres. The following table shows the comparative acreage, production and value of the important crops for 1909 and 1919:—

|                |      | Acreage   | Production      | Value in \$ |
|----------------|------|-----------|-----------------|-------------|
| Corn           | 1909 | 3,146,348 | 67,682,489 bu.  | 45,819,093  |
|                | 1919 | 3,301,075 | 70,639,252 bu.  | 127,150,649 |
| Oats           | 1909 | 342,086   | 4,720,692 bu.   | 2,378,464   |
|                | 1919 | 162,417   | 2,413,409 bu.   | 2,534,082   |
| Wheat          | 1909 | 619,861   | 6,516,539 bu.   | 6,913,335   |
|                | 1919 | 684,497   | 6,362,357 bu.   | 14,506,174  |
| Hay and Forage | 1909 | 1,060,480 | 1,100,838 tons  | 12,784,783  |
|                | 1919 | 1,751,123 | 1,907,345 tons  | 49,649,657  |
| Cotton         | 1909 | 787,516   | 264,562 bales   | 17,966,517  |
|                | 1919 | 807,770   | 306,974 bales   | 48,808,866  |
| Tobacco        | 1909 | 90,468    | 68,756,599 lb.  | 5,661,681   |
|                | 1919 | 138,561   | 112,367,567 lb. | 24,720,869  |

The value of vegetables sold in 1919 was \$27,947,250, and of fruits and nuts \$7,888,712. The number of the principal domestic animals on Jan. 1 1925 were: horses, 291,000; mules, 326,000; cattle, 1,026,000; sheep, 319,000; and swine, 1,071,000.

In 1920 there were 11,836,303 fowls valued at \$10,591,690 and 191,898 hives of bees valued at \$698,258. In 1919 the reported milk production was 115,119,224 gal.: the value of milk, cream, and butter-fat sold and of butter and cheese made was \$20,640,849. The Smoky Mountain area (59,213 ac. in Blount and Sevier counties) and the White Top area (33,619 ac. in Johnson and Sullivan counties and Washington county, Va.) were approved for purchase in 1912 by the National Forest Reservation Commission under the Federal Act of March 1 1911, to preserve the upland watersheds. In 1920, 254,118 ac. of farm land were reported as provided with drainage and 640,479 ac. as needing drainage. Capital invested in drainage enterprises Dec. 31 1919 totalled \$2,925,944.

*Mineral Products.*—Tennessee produces most of the copper mined in the Southern States. Its entire production of copper, gold and silver comes from mines worked primarily for copper in Polk county. Lead production commenced in 1915 (1,660 lb.), amounted to 3,144,000 lb. in 1924. The silver output was 39,525 oz.; copper, 18,240,150 lb.; zinc, 42,660,894 pounds. Because of low prices and strikes the coal amounted to only 4,750,754 tons in 1924. The demands of the World War led to the working of known manganese deposits in 16 counties, but only one mine was in operation in 1924. In 1925 oil was being produced in Scott, Clay, Fentress and Pickett counties, and other wells were being bored in these counties (see PETROLEUM). In 1910 natural gas was found near Franklin. In 1924 the production of phosphate rock was 318,642 tons; marble valued at \$2,214,000 was mined; 358,857 tons of sulphuric acid produced; and 127,236 tons of pig-iron. The total value of mineral products in 1923, exclusive of pig-iron, was \$44,185,381. Coal was mined on 4,400 sq. m., the produce being 6,040,268 tons.

*Manufactures.*—In 1921 there were 2,245 establishments employing 9,865 salaried officials, and 75,446 wage-earners. The salaries amount to \$21,581,000, and the wages to \$65,741,000. The cost of material was \$225,951,000, and the value of product \$374,038,000. Flour and grist-mill products, cotton-seed oil and cake, lumber and timber products, food preparations, cotton goods and foundry and machine shop products were the most important manufactured goods.

*Transportation.*—On Jan. 1 1923 the total railway mileage of the State was 4,022 m. or 9.6 m. per sq. m. of land area. The chief railways were: Louisville & Nashville, 952 m.; Nashville, Chattanooga and St. Louis, 903 m.; Southern Railway, 891 m.; Tennessee Central, 291 m.; Illinois Central, 143 miles.

*Finance.*—The balance in the State Treasury July 1 1924 was \$7,890,200. Receipts for the fiscal year ending June 30 1925 were \$20,705,266, and disbursements \$21,964,634. On June 30 1924 the total funded debt was \$14,703,000.

*Education.*—By an Act of 1909, State normal schools were established in Johnson City, Memphis, Murfreesboro, and (for negroes) in Nashville. Tennessee Polytechnic Institute was established by Act of the legislature in 1915. By an Act of 1917 the State loaned the University of Tennessee \$1,000,000 for building purposes; and by an Act of 1925, an additional \$350,000. In 1924 the total school population was 770,500. The enrolment in the public schools was 658,196 and the average daily attendance was 448,045 (368,888 in 1912). The number of teachers was 15,695, of whom about 12,000 were women. In 1919 the compulsory school age was raised from 14 to 16 years. In 1925 an Act was passed authorising the raising of teachers' salaries, and the fixing by each county of a rural school term of at least eight months.

*History.*—In 1910 Benjamin W. Hooper was elected governor, following a serious split in the Democratic party over the prohibition question. He was the only Republican elected to State office, and was the first Republican governor since 1883. In 1911 the Legislature chose Luke Lea to succeed U.S. Senator James B. Frazier. In 1912 Hooper was renominated for governor and was re-elected over Benton McMillin (governor 1899-1903), the

Democratic candidate. Robert Love Taylor, U.S. Senator from 1907, died 1912, and as his successor to the Senate, the Legislature in 1913 chose John K. Shields, a member of the State supreme court since 1902 and chief justice since 1910. In the presidential election of 1916, Wilson received 152,055 votes and Hughes 116,257. In 1920 Harding received 219,829 votes and Cox 206,558. For the first time since 1868 the Republican presidential candidate carried the state. A Republican governor, A. Taylor, also was elected. In 1922 Austin Peay (Dem.) was elected governor and re-elected in 1924. Lawrence D. Tyson (Dem.) defeated John K. Shields for U.S. Senator in 1924. In the same year, in the presidential election, Davis received 158,537 votes, Coolidge 131,064 and La Follette 10,732.

An Act prohibiting the manufacture of intoxicating liquor in the State became effective Jan. 1 1910; in Oct. 1913, Gov. Hooper called a special session of the Legislature and secured passage of the so-called nuisance bill, intending to close every saloon in the state, and forbidding the sale of intoxicating liquor within four miles of any school; in 1915 provision was made for removal from office of State, county or city officials who failed to enforce the prohibition law; on Feb. 2 1917 Gov. Rye signed a bill forbidding the importation of liquor into the state. The hours of labour for women were reduced to 58 per week after Jan. 1 1914 and to 57 after Jan. 7 1915. In 1913 an Act was passed providing "that married women be and are hereby fully emancipated from all disability on account of coverture, and the common law as to the disabilities of married women and its effect on the rights of property of the wife is totally abrogated."

In 1915 a law was passed providing for mothers' pensions. In 1917 the letting of prison labour to private contractors was prohibited, and an Act was passed forbidding the limiting of the output of coal in order to increase the price. The same year a State Budget Commission was created. On Aug. 18 1920, the House, by 50 to 46, voted to concur in the Senate resolution (adopted Aug. 13, by 5 to 4) ratifying the proposed amendment to the Federal Constitution, providing for woman suffrage. As the 36th State (out of the 48 in the American Union) to ratify, Tennessee brought the number to the requisite three-fourths.

Recent governors have been: Malcolm R. Patterson (Dem.) 1907-11; Benjamin W. Hooper (Rep.) 1911-5; Thomas C. Rye (Dem.) 1915-9; A. H. Roberts (Dem.) 1919-21; Alfred A. Taylor (Rep.) 1921-3; Austin Peay (Dem.) 1923-.

(C. E. A.\*; H. A. M.)

**TENNIEL, SIR JOHN** (1820-1914), British artist (see 26.626), died in London Feb. 25 1914.

**TENNIS** (see 26.626), a game which has made steady progress since 1910 and stands in a stronger position to-day in England and America than at any former time in its modern history. In France it is not so flourishing, and it is regrettable that in Paris, once the headquarters of the game, there are now only a few players.

In Great Britain there are 41 tennis courts standing, 27 of which are in regular or occasional use. In America there are 13 in use; France has nine courts, of which three are available for the game; the Irish Free State has two courts; Australia one; Tasmania one, and Austria one. Courts built since 1910 include Mr. J. F. Marshall's at Sea Court, Hayling Island (1911); the Hon. Cecil Baring's on Lambay Island, begun before the World War and finished afterwards; Mr. Payne Whitney's, Greentree, Long Island (1915) and the Chicago Racquet and Tennis Club (1924). Those which have been renovated or re-opened include the court at Canford School, near Wimborne, W. N. McClean's at Rushall House, Tunbridge Wells, the court at Leamington and that at Pau.

Chief among the new competitive events is the Bathurst Cup, for competition among amateur international teams. This is played in London and Paris in alternate years. Others are the professional invitation handicap promoted by the British Tennis and Racquets Association, the coupe de Pau, open to all amateurs, the British inter-club four-handed championship and the old public schoolboys competition. The open championship of the game was held in 1910 by C. (Punch) Fairs, formerly of

Princes' Club and now with Mr. Clarence Mackay in America. In 1912 G. F. Covey, professional to Baroness Wentworth at Crabbet Park, Sussex, defeated Fairs, and he is the present holder of the championship. Since the War he has twice defeated Walter Kinsella of New York for the honour.

The leading amateurs since 1910 have been Jay Gould in America and the Hon. N. S. Lytton and E. M. Baerlein in England. Gould is generally held to be the finest amateur the game has produced. Lytton has not appeared in competitive play since 1913. Baerlein first won the British amateur championship in 1912 and since 1914 has held it without a break. Other well-known amateurs during the period have been, in England, E. H. Miles, whose last appearance was in 1914, V. H. Pennell, J. F. Marshall, Capt. R. K. Price, E. A. C. Druce, the Hon. C. N. Bruce and R. H. Hill; in America, Joshua Crane, C. S. Cutting and Hewitt Morgan; in France, William Bazin, Paul Deves, J. Worth and Comte du Vivier. The Tennis and Racquets Association was re-organised after the War and its scope extended. It has done valuable work in many ways, particularly in organising and supporting matches and competitions among professionals. The chief addition to the bibliography of the game has been E. B. Noel and J. O. M. Clark, *A History of Tennis* (1924).

(E. B. N.)

**TERRY, EDWARD O'CONNOR** (1844-1912), British actor (see 26.660), died in London April 2 1912.

**TERRY, SIR RICHARD RUNCIMAN** (1865- ), British organist and choir-director, was born at Ellington, Northumberland, the son of Thomas Terry of Newcastle-on-Tyne and obtained a choral scholarship at King's College, Cambridge. After acting as organist and choirmaster at Elstow School (1890); St. John's Cathedral, Antigua, West Indies (1892); and at Downside Abbey near Bath (1896), he became organist and director of the Roman Catholic Cathedral, Westminster, London (1901-24). He was knighted in 1922, his musical research work having been of the highest importance. He edited the beautiful church music of numerous Tudor composers (Byrd, Taverner, Tallis and others), hitherto unpublished, which was performed with great perfection by his choirs. He was the composer of five Masses and other music, and the author of *Our Church Music* (1901); *Catholic Church Music* (1907); *Tudor Church Music* (1922); etc.

**TESCHEN** (Czech *Těšín*, Polish *Cieszyn*; see 26.664), a town and district of Poland and Czechoslovakia. Teschen lies in the southeast corner of Silesia, and was a duchy disputed between the kings of Poland and Bohemia from the 9th century onward. On the 17th century it came under Habsburg rule. It is 852.6 sq. m. in extent. It is rich both in coke and gas coal, and is an important strategic centre of roads and railways, especially of the Bohumin (Oderberg) line. Its population in 1910 was 426,370, of whom 54.85% spoke Polish, 27.11% Czech and 18.04% German.

At the Peace Conference in 1919 the Czechs were much incensed to discover that Polish deputies had been elected in Teschen, for the representatives of the two nations had already decided in May-June 1918 to settle the dispute by friendly agreement. Czech troops actually advanced and occupied Oderberg in Jan. 1919; the Great Powers then intervened and decided (Sept. 27 1919) to hold a plebiscite under the auspices of the Principal Allies, not only for the Duchy of Teschen but also for the adjacent Suvan areas of Spiš (Zips) and Orava. This commission did not arrive until Jan. 1920, when they were confronted with riots, strikes and other difficulties. They appealed to the Conference of Ambassadors at Paris, which, on July 28 1920, abandoned the plebiscite plan and induced both Czechs and Poles to agree to a partition. The Spiš-Orava areas offered few difficulties. In the duchy itself the Czechs obtained the Karvinná (Karwin) mining area and the Oderberg-Jablunkov railway, the Poles the town of Teschen, except its western suburb, and an agricultural area. The economic unity of the duchy was preserved by an arrangement which afterwards served as a model for the partition of Upper Silesia.

See H. W. V. Temperley, *History of Peace Conference*, vol. 4 (1921), chap. 6, Pt. 1, by R. Fitzgibbon Young. (H. W. V. T.)

**TESLA, NIKOLA** (1857— ), American inventor, was born at Smiljan, Lika, Austrian Croatia. He graduated from real schule, Karlstadt, in 1873, and studied at the polytechnic school, Graz, Croatia, and the University of Prague, intending to specialise in physics and mathematics, but became interested in electricity. He was first employed in the Austrian Govt. telegraph engineering department, later being engaged in electrical engineering in Budapest and Paris. He went to the United States in 1884. For a time he was with the Edison Co. at Orange, N. J., but relinquished his position in order to devote himself to research, for which purpose he established the Tesla laboratory in New York City. He was the first to conceive an effective method of utilising the alternating current and in 1888 patented the induction motor, by means of which electrical energy might be converted into mechanical energy more effectively and economically than by the direct current. He invented the principle of the rotary magnetic field embodied in the apparatus used in the transmission of power from Niagara Falls. He also invented new forms of dynamos, transformers, induction coils, condensers, arc and incandescent lamps and other electrical apparatus.

**TESTING MACHINERY** (see 25.1010a).—Machinery employed in the determination of the mechanical properties of bodies, or, in the widest sense, the complete relations between load and distortion. Since the conditions which prevail during the determination of any such relationship have a great effect upon the results—a large number of accurate physical measurements are required for a reasonably complete statement of the mechanical properties of a body. The term "machinery" includes the delicate instruments which are necessary for many of these measurements.

*Purpose of Tests.*—The main objects of the tests which are carried out with the aid of testing machinery are: (1) to determine with the greatest possible accuracy the behaviour of materials when loaded; (2) to furnish criteria for the selection and for the manufacture of materials of definite properties, and to insure that such properties are obtained; (3) to furnish criteria for the design of articles constructed from such materials to withstand defined conditions of loading, and to insure that such articles conform with requirements. In the present state of knowledge many of the criteria are necessarily of a tentative kind.

The information required in recording the results of a test includes the nature of the material, the shape, size and temperature of the body, the intensity of the load and the manner in which it is applied. The functions of testing machinery are to apply the required loads to pieces of specified material of specified shape under definite conditions, to measure the intensity and conditions of application of those loads and to measure the resulting distortions of the pieces under test.

*The Material and Its History.*—A description of the nature of the material involves as complete a statement as possible of its natural and industrial history, and of its chemical and physical constitution. The importance of this information is now more fully realised than formerly. An accurate test result may be rendered of very small value by the absence of such data, because relatively large differences in mechanical properties may be correlative with apparently small differences in the constitution of the material.

The conditions under which a test is to be carried out require some consideration. When a load is applied to a body, the body suffers a change of form which varies with the load and with its manner of application, and depends also upon the original shape of the body and upon its physical condition. It is convenient, therefore, in comparing one material with another to deal with pieces of standard shape to which loads are applied in a standard manner; but the relative behaviour of two materials may be different if the form of the standard shape be altered or if the load be applied in some other standard manner. In testing finished articles it is accordingly wise to apply the load in a manner which conforms as closely as possible with the expected conditions of loading when the article is in everyday use.

As a rule the change of shape of a body cannot be continued

indefinitely, but reaches a limit at which the body breaks. The load which is necessary and sufficient to cause fracture is called the strength of the body under the given conditions, and is of course an important mechanical property.

*Standard Shape.*—The standard shape most usually employed in tests of materials is that of a cylinder or of a rectangular prism. It is not possible to arrange that all test pieces of standard shape shall be of the same size; the dimensions of pieces of different size are arranged to be as nearly as possible in accordance with the principles of similitude.

The standard manner of loading the test piece may be such that at any cross section of the piece the internal forces in the material are equivalent to a single force; this is called direct loading. Or the load may be applied in such a way that the internal forces at a cross section of the material are equivalent to a couple, or to a force combined with a couple; this is called momental loading. In direct loading the applied force may be a pull or a push, giving rise to lengthening or to shortening respectively of the test piece. In momental loading the applied couple may lie in a plane parallel to that of a cross section of the test piece or in a plane at right angles thereto, giving rise to twisting or to bending respectively. In combined loading the piece is subjected to two or more systems of externally applied load.

The rate of loading is of importance because the distortion of a body requires time for its accomplishment. In so-called static tests the load is applied to the test piece slowly and without shock. In impact tests the load is applied abruptly as a blow. Fatigue tests require the repeated application of a load insufficient, when only once applied, to cause the failure of the test piece.

*Variety of Tests and Machines.*—Such variety of procedure necessitates a corresponding variety in the machines in which the tests are to be performed. Many machines are built which will carry out all the usual static tests, tension, pressure, bending and twisting, as well as others not so frequently employed, such as punching, shearing, drifting and bulging; these are sometimes termed universal machines. They have the disadvantage that a change in the kind of test necessitates more or less extensive alteration in the movable fittings of the machine. When only pieces of a definite standard size are to be accommodated this difficulty may be overcome by suitably designing the machine. If the articles to be tested are of considerable variety in size and shape it is more convenient to have a separate machine for each kind of test; but it is well to provide a measure of adaptability for unusual tests and odd sizes of articles.

*Complex Stresses.*—In tests where complex stresses are involved, and the effect upon the experimental results of a change in the dimensions of the test piece, or in other conditions, is not amenable to reasonably accurate calculation, it becomes necessary to define rigidly the design and manner of operation of the testing machine and the dimensions of the test piece. In some degree this arbitrary choice of conditions applies to all tests, and it indicates our limited knowledge of the relations between load and distortion. Thus for a metal bar broken by pulling, the degree of stretching of any region of the bar varies with the longitudinal position of that region; for the purpose of a rational comparison the stretch must be made referable to a uniform length in bars of uniform size, or to properly proportionate lengths in bars of different sizes, and the choice of standard lengths is governed chiefly by their general convenience for testing purposes. In other cases the arbitrary nature of the conditions of test is more evident, as for instance in the determination of the "setting time" of cement, in the dimensions of the impact bending machine and its test piece, and in the determination of the "wear" of paving materials. In such cases the results allow of the comparison of the behaviour of pieces of similar form under complex but rigidly controlled conditions. If those conditions are well chosen the test results may be correlated with the behaviour of pieces of similar material in actual use; if correlation cannot be eventually established the test is of little value.

**Mode of Operation.**—Testing machines for static tests are usually operated either directly by hydraulic power or through intermediate gearing by a heat engine or an electric motor; small machines are operated by hand through gearing. For comparable results it is desirable to obtain close regulation either of the rate at which the load is applied or of the rate at which the test piece is deformed, but though such regulation has been accomplished in many circumstances it is not readily attained in general testing. The forces are transmitted to the test piece through special bearing pieces and other fittings, which must be carefully designed to secure the intended distribution of load. The forces are usually measured either by means of a lever system and weights, or by some form of hydraulic gauge. In impact tests the source of energy is nearly always a falling weight, frequently arranged as a pendulum, and the energy of the weight is measured before and after the blow. Repetitive tests involve either a rotary or a reciprocating motion, and this is generally derived from an electric motor. The load is applied directly by weights or by springs, with dashpots to damp vibrations, or by a magnetic arrangement or indirectly by the inertia of the moving parts of the machine.

The dimensions of the test piece and the changes in its dimensions, unless they are large enough to allow of direct measurement to a sufficient degree of accuracy, are obtained by means of instruments which magnify either mechanically or optically or by a combination of these methods.

Some description and illustration of testing machines and apparatus is to be found in the article "Strength of Materials" (see 25.1007). These and similar appliances are in everyday use and yield useful and accurate information. But the whole subject is now on a wider basis than formerly, chiefly as the result of investigation of the constitution and structure of materials. The coarser details of structure have been revealed by visual and by microscopic examination, while the minute details of crystalline, colloidal and atomic structure have been deduced from various kinds of physical measurements. Certain fundamental mechanical properties have been placed upon a physical basis. Many problems of stress distribution have received useful mathematical solutions. Many other such problems have been solved experimentally, notably by Coker using the photo-elastic method<sup>1</sup> and by Griffith and Taylor using the soap-film method.<sup>2</sup> More extensive study of stress-strain relations has been facilitated by the recording device of Dalby<sup>3</sup> and by the cinematograph. Many details of the manner and progress of deformation and fracture have been revealed by research.<sup>4</sup> (See CRYSTALLOGRAPHY; METALLOGRAPHY.)

Recent explorative work, carried out by means of apparatus more fitly described as machinery than the delicate instruments required for the researches mentioned above, has been chiefly concerned with combined systems of static loading, repetitive loading, impact loading and various methods of measuring hardness. Experiments on combined static loading received their chief impetus from the results obtained by Guest,<sup>5</sup> and are directed to the determination of the relations which exist between the principal stresses and the principal strains in complex stress systems. In tests by repetitive loading the early work of Wöhler has been extended to the improved materials now available. Many new types of machines have been devised, and some of these apply complex systems of loading. Ingenious methods of measuring distortion allow of rapid estimation of the limits of endurance, and attempts have been made to correlate the quantitative results of tests with microscopic observations of structural change in the material.<sup>6</sup> Impact tests have been standardised, but more work is required to place such tests upon a satisfactory scientific basis. Progress has been made in establishing relations between hardness and other properties of a material, and new methods of obtaining more accurate measurements of hardness have been devised.<sup>7</sup>

The results of these and similar researches have led to the manufacture of improved and even new materials, to increased precision and stringency in specifications, to improvements in

testing machines and apparatus and to greater care and accuracy in testing. But we are still far from the day when a few simple measurements may allow the mechanical behaviour of a material under any conditions of loading to be deduced.

For tests of bridges and other large structures, the apparatus must be brought to the structure, which is then loaded by dead weight or by moving vehicles in appreciably heavier degree than it is expected normally to undergo. Measurements, interpreted with knowledge of the principles of design, of the distortion at regions of severest stress, combined with an examination of those regions of the structure while under load, afford a reliable indication of the resistance of the structure. Special instruments have been devised for convenience in measuring distortions of large structures.

**TETANUS or LOCKJAW** (see 26.669).—On the appearance of tetanus in the British Army during the early days of the retreat from Mons immediate steps were taken to cope with it. The disease could be prevented if a dose of anti-tetanus serum were given as soon as a wound was sustained because some days elapse before the bacilli, which remain in the wound, are able to secrete sufficient poison to precipitate an attack. From that time every wound, no matter how slight, was followed as soon as possible by a dose of anti-tetanic serum. Out of 1,242,000 wounded men who were sent home to England, 1,458 cases of tetanus arose, giving a ratio of rather more than 1 per 1,000. In Sept. 1914 the ratio of tetanus cases to wounds was 9 per 1,000. In Oct. 1918 the ratio was 0.5 per 1,000.

In Nov. 1914 preventive inoculation, introduced about the middle of Oct. 1914, had begun to exercise its beneficial effects. The following figures giving the number of cases of tetanus per 1,000 wounded men make this clear:—

|                  | Cases of tetanus |                  | Cases of tetanus |
|------------------|------------------|------------------|------------------|
| Sept. 1914 . . . | 9.0              | Feb. 1915 . . .  | 1.1              |
| Oct. 1914 . . .  | 7.3              | March 1915 . . . | 0.4              |
| Nov. 1914 . . .  | 2.3              | April 1915 . . . | 2.3              |
| Dec. 1914 . . .  | 1.4              | May 1915 . . .   | 0.8              |
| Jan. 1915 . . .  | 0.0              | June 1915 . . .  | 0.2              |

The same experience was met with in the French and German Armies. As soon as preventive inoculation with anti-tetanic serum became a universal practice the incidence of tetanus dropped sharply and remained small. In June 1917 it was ordered that each wounded man should receive not one inoculation as formerly but four, at intervals of a week, because the minimising effect of the serum passes away rather quickly.

The effect is not always to prevent absolutely. But even in those cases in which tetanus does supervene in spite of the inoculations, the incubation period is lengthened and the death rate is lowered; other things being equal, a long incubation period tends to result in a milder attack than a short incubation period, thus any circumstance prolonging the incubation period will also tend to lower the death rate. Only 26.9% of the inoculated are attacked during the first fortnight, whereas 68.9% of the uninoculated are attacked. Among the protected 40.0% have an incubation period of more than 35 days; among the unprotected only 6.5%. The average incubation among inoculated is 45.5 days, among uninoculated 10.9 days. Indeed, in each year of the War the incubation period tended to rise. Further, the inoculations tended to limit the degree of tetanus, converting what would be generalised cases into local or one-limb cases. The following table illustrates this:—

<sup>1</sup> Figures throughout the text refer to notes in the Bibliography.

| Tetanus type | Percentages |      |      |      |      |
|--------------|-------------|------|------|------|------|
|              | 1914        | 1915 | 1916 | 1917 | 1918 |
| General      | 98.9        | 98.6 | 87.0 | 76.6 | 83.5 |
| Local        | 1.1         | 1.4  | 13.0 | 23.4 | 16.5 |

Local tetanus tends to occur in the wounded or injured limb and to be confined to that limb. It is much less severe and far less fatal than the generalised type. Naturally the death rate reflected these successes. Among the unprotected and unrecorded the death rate per cent was 53.5. Among the protected it was 23.0. The "unrecorded" here undoubtedly include cases which had received a dose. The method employed during the War fully justified the hopes which were entertained concerning it.

**BIBLIOGRAPHY.**—Maj.-Gen. Sir David Bruce, K.C.B., F.R.S., *The Prevention of Tetanus During the Great War by the Use of Anti-tetanic Serum*, Research Defence Society, Form D2 (July 1920).

**TEWFIK, AHMED PASHA** (1845— ), Turkish statesman, was born in Constantinople Feb. 11 1845, the son of Ismail Hakki Pasha. In 1866 he went to the Ministry of foreign affairs, where he spent six years. After acting as first secretary to the Turkish Legation in Athens, he was sent to St. Petersburg (Leningrad), where in 1877 he received Prince Gorchakov's note declaring war. The following year he became Turkish minister in Athens, in 1885 he went to Berlin as ambassador, and remained there for 10 years. In 1895 he was appointed minister of foreign affairs, which post he filled during 14 years; and on the termination of the Greco-Turkish War it was he who signed the peace treaty with Greece in 1898. After the Young Turk revolution he became grand vizier, and in 1909 he was sent to London as ambassador, where he remained till 1914. In 1919 he was reappointed grand vizier, afterwards becoming president of the Senate, and in 1921 he attended the London Conference arranged by the Supreme Council of the Allies. The following year he retired into private life. During his long career of more than 60 years, Tewfik Pasha played an important part in Turkish affairs. His conciliatory spirit won him universal admiration and the agreements which he concluded with the Balkan States did much to improve relations between these States and Turkey.

**TEXAS** (see 26.688), a State of the United States of America. In 1923 the population was 4,939,630, as against 4,663,228 in 1920 and 3,896,542 in 1910, an increase since 1920 of 276,402, or 5.0%, as against 19.7% in the decade from 1910-20. The urban population (in places of 2,500 or more) was estimated at 1,605,380 in 1923 or 32.5% of the total, as compared with 32.4% in 1920. The average number of inhabitants per sq. m. increased from 14.8 in 1910 to 17.8 in 1920 and to 18.8 in 1923. The estimated population for 1925 was 5,097,574. The following table shows the growth of the cities having, in 1920, a population of more than 100,000:—

| City        | 1924 (Est.) | 1920    | 1910   | Increase % |
|-------------|-------------|---------|--------|------------|
| San Antonio | 191,308     | 161,379 | 96,614 | 67.0       |
| Dallas      | 187,862     | 158,976 | 92,104 | 72.6       |
| Houston     | 163,554     | 138,276 | 78,800 | 75.4       |
| Fort Worth  | 148,107     | 106,482 | 73,342 | 45.2       |

**Agriculture.**—The 1910 census gave Texas 417,770 farms with a total area of 112,435,067 ac., of which 27,360,666 ac. were improved. The 1920 census showed 436,033 farms, with a total area of 144,020,521 ac., of which 31,227,503 ac. were improved. This was an increase in improved farm land of 3,866,837 ac. between 1910 and 1920. The value of all farm property in 1920 was \$4,447,420,321. The principal crops of 1924, in the order of acreage, were cotton, corn, oats, grain sorghum, wheat, hay, rice, barley, peanuts, sweet potatoes, sorghum syrup, watermelons, broom corn, rye and onions. These crops covered 27,981,000 ac.; their farm value, partly estimated, was \$789,117,000. In 1919, at the peak of post-war prices, their value was \$1,051,817,000. Texas is a large producer of fruits and vegetables. The average annual yield of corn, 1911-9, was 126,600,000 bu.; 1919-24,

130,805,666 bu.; of wheat, 1911-9, 15,300,000 bu.; 1919-24, 20,552,000 bu.; of cotton, 1911-24, 3,651,000 bales.

**Livestock.**—The following table shows the numbers and values of livestock in 1921 and 1924 (figures of U.S. Dept. of Agriculture) (000's omitted):—

|              | 1921               |                     | 1924   |             |
|--------------|--------------------|---------------------|--------|-------------|
|              | Number             | Value in \$         | Number | Value in \$ |
| Range Cattle | 4,500              | 213,184             | 5,597  | 139,183     |
| Milch Cows   | 1,840              | 1,063               | 1,063  | 1,063       |
| Horses       | 1,187              | 89,000              | 980    | 53,900      |
| Mules        | 800                | 84,744              | 854    | 73,344      |
| Sheep        | 3,000 <sup>1</sup> | 19,335 <sup>1</sup> | 3,097  | 18,272      |
| Swine        | 2,427              | 28,639              | 2,165  | 17,136      |

<sup>1</sup> 1920.

**Minerals.**—The most important mineral products are oil, sulphur, coal and lignite. At the beginning of 1925 there were 90 producing oil fields, covering all sections of the State. The Humble field in Harris county was opened in 1905, Goose Creek in 1911, and Blue Ridge and the West Columbia field in Brazoria county in 1919. The Burkburnett field in Wichita county first became important in 1917, Ranger in Eastland county in 1917, and Desdemona and Breckenridge in Comanche, and Stephens counties respectively in 1918. In 1922 an important field was discovered in Reagan county on land belonging to the University of Texas. Production dropped from 28,000,000 bbl. in 1904 to less than 9,000,000 in 1910; rose to 27,644,000 in 1916; 32,413,000 in 1917; 38,750,000 in 1918; 85,312,000 in 1919; and 128,847,156 in 1924 (see PETROLEUM). The value of natural gas marketed in the State rose from \$127,000 in 1909 to \$10,623,000 in 1922; natural gasoline in 1923 amounted to 177,765,000 gallons.

Two sulphur plants in Texas and one in Louisiana were said, in 1920, to yield 98% of all the sulphur produced in the United States. One of the Texas plants is at Freeport, near the mouth of the Brazos river; the other is near Matagorda, close to the mouth of the Colorado. The Freeport plant began producing in substantial quantities in 1916, and the next year, under war pressure, delivered 500,000 tons a year. The yield of bituminous coal in 1923 was 175,332 tons. Lignite is mined chiefly for home consumption; the 1923 yield was 1,011,997 tons. Other minerals of fairly steady yield are silver, worth about \$500,000 per annum, quicksilver, cement and clay products. Quicksilver is produced at the Terlingua mine in Brewster county; the highest yield recorded, 10,791.75 lb. in 1917, was valued at \$1,136,502. Cement production in 1924 was 4,400,000 bbl., valued at \$9,500,000. Clay products (brick, tile and pottery) in 1923 were valued at \$4,800,000. Salt is produced in fairly steady quantities, and in 1920 yielded 91,103 short tons, with a value of \$667,835.

**Manufactures.**—In 1920 there were 5,724 manufacturing establishments, capitalised at \$585,776,451, employing 107,522 persons, and producing an annual value of \$999,995,796, of which \$298,824,898 was value added by manufacture. The principal industries were those concerned with lumber; cotton and cottonseed products; printing and publishing; oil refining and allied products; flour and grist-milling and food preparations. The lumber production was 1,500,000 ft. for 1924, when Texas ranked sixth in this industry, as it had done in 1910 and 1915.

**Commerce.**—The chief ports are Sabine, Port Arthur, Orange and Beaumont in the Sabine district, importing chiefly crude oil and exporting refined oil and oil products; and Houston, Texas City, Freeport and Galveston in the Galveston district, which export cotton, grain and sulphur. The port of Houston was opened in 1915, its access to the Gulf of Mexico being through the Houston ship channel, formed by the widening and deepening of Buffalo Bayou. The distance from the municipal docks to the gulf is 54 miles. Unofficial figures for 1924 fixed the value of imports through Galveston, including the subsidiary ports of the district, at \$37,354,862, and the exports at \$547,632,800, making Galveston second to New York as an exporting port in the United States, a position which it had held for some years. These figures did not include coastwise traffic. In 1923 the tonnage

passing through the ports of the Galveston district was 12,451,811. In 1920, 1,233 vessels cleared for foreign ports, of which 849 were American, 222 British, 29 Norwegian, 26 Italian and 18 Mexican. The bulk of their cargoes was made up of 2,126,717 bales of cotton and 44,726,000 bu. of wheat.

*Finance.*—The value of all property assessed for State taxation on Aug. 31 1924 was \$3,419,091,814. The ratio of assessed value to real value varied from 66% in some cities to 25% in some rural districts. The total receipts of the State Treasury for the year were \$34,849,557.81, and total expenditures \$34,849,557.81. On June 30 1924 there were 846 State banks in operation, 176 of which were members of the Federal reserve system in 1921. On Oct. 10 1924 there were 576 national banks in operation.

*Education.*—For 1925 the school population (seven to 18 years of age) was 1,335,000; and the number of teachers employed in public schools (1924) was 35,459, of whom 4,347 were negro. The practice of making legislative appropriations to supplement the available school funds began in 1915. A compulsory attendance law became effective in 1918. A law of April 3 1918 requires all public school work to be conducted in the English language.

*Administration.*—The Industrial Accidents Board was created in 1913, primarily to administer the Employers' Liability Act. The Board of Water Engineers was created in 1913 to regulate the use of public water for irrigation and all other purposes. The Highway Commission, established in 1917, is charged with the administration of all highway laws, including that of the registration of motor vehicles. On Nov. 1, 1924, there had been completed under its supervision 17,000 m. of approved highways, costing \$28,687,095; at the same time contracts were in progress for the construction of 1,812.57 miles. The Commission reported the registration during 1924 of 801,080 automobiles and trucks and 2,324 other motor vehicles. The State Board of Control was created in 1920, in an effort to consolidate administration and to co-ordinate the State budget. The Railroad Commission reported in Dec. 1923 15,860.71 m. of railroad in operation, a decrease of 231.14 m. since 1922.

*History.*—A constitutional amendment providing for State-wide prohibition was voted down in 1911. Prohibition by local option made great progress, however, and by 1918 more than three-fourths of the area of the State—including the cities of Dallas, Waco and Austin—was dry. The Legislature in March 1918 ratified the Federal amendment and in April put into effect the "zone" law prohibiting the sale of liquors within 10 m. of a military, naval or ship-building establishment. In June 1918 statutory State-wide prohibition was established, and doubts of the constitutionality of the Act were ended by the carrying of the amendment for State-wide prohibition in 1919. A law of March 26 1918 permitted women to vote in party primaries and nominating conventions; but a constitutional amendment, submitted the next year, to enfranchise women in regular elections failed. The legislature, nevertheless, ratified the Federal woman suffrage amendment in July 1919. The effect of the World War is seen in a law of April 2 1918, confining the franchise in primary elections to citizens of the United States; and in another of March 23 1918, amended a year later, providing that assistance should be given at the polls in the English language only and to persons physically unable to write or to those past 60 years of age and unable to write.

The governors of Texas after 1910 were: Oscar Branch Colquitt (Dem.), 1911-5; James E. Ferguson (Dem.), 1915-7 (impeached); William P. Hobby (Dem.), 1917-21; Pat M. Neff (Dem.), 1921-4; Mrs. Miriam A. Ferguson (Dem.), 1924- . (E. C. BA.)

**TEXTILE MACHINERY.**—A so-called artificial wool has been placed on the market; but it still is far from the natural wool fibre. Should a reasonably satisfactory artificial wool fibre be ultimately produced it will be necessary to devise particular processes and machines for its manipulation along the lines at present in use for English wool "drawing" and "spinning."

*Artificial Wool.*—If the present artificial wool is prepared and spun into yarn on the French system—a system which should give the fullest possible thread and resultant cloth—it is still too

solid for the French type of fabric, partaking more of the character of a Peruvian cotton yarn than of a Botany yarn. Therefore, the processes of manufacture and the machines for carrying out these processes will have to ensure greater fullness or, on the other hand, a characteristic hardness and lustre; the development of necessary processes and machines for attaining one or other of these ends in the near future may become a dominant feature in the industry. As the differences observable in dyeing artificial wool as against natural wool give rise to changes in machine design, the coming of artificial wool—if and when it does appear—will lead to the evolution of processes of manipulation and machines to carry them out.

*Structural Improvements.*—Referring to structural improvements in textile machinery, attention should be directed to the increased employment of "Chain drives" and "Roller and ball bearings." The tendency toward more positive control has naturally favoured the use of chains in cards, looms, etc. The increase in roller and spindle speeds in carding, combing, drawing and spinning have called for experimental work with roller or ball bearings in order to reduce wear of parts, better or simplified oiling and accuracy in setting. Opinion is still divided as to the merits of roller or ball and plain bearings respectively. Noble comb circles certainly seem to be improved in running if run on ball-rolls but many carding engineers still prefer the plain bearing.

In those sections of the industry where little improvement in manipulating skill has been called for, little or no advance has been made, whereas in those sections where there has been a constant pressure conducing toward efficiency, there has been a steady advance in the perfecting of details, which in the aggregate total up to a considerable move forward. Thus in the wool industry, owing to ladies' fashions favouring a small area of body covering of a medium to heavy weight, pressure has been taken off efficiency in fine yarn spinning, and about one-quarter of the spinners and weavers are required for a given production as compared with, say the "crinoline" period of 1860. The pressure toward efficient output has also been removed. Should fashions change toward lighter fabrics requiring finer yarns, the industry will need speeding-up machines and processes.

*The Preparatory Processes.*—The thorough cleansing of wool preparatory to combing and spinning is still under serious discussion. Broadly speaking, most firms have usefully stabilised both their scouring liquors and their method of mechanical control. A firm in the Roubaix district, however, being convinced that to scour wool in its own wash-water products is the most natural and best process, has designed the necessary mechanical control to effect this. The patentees claimed that a softer, opener wool is delivered under this process as compared with similar wool treated on the normal lines, i.e., without preliminary steeping.

Petrie's "self-cleaning bowl" for wool-washing is proving useful in many cases where with the normal bowl a very variable result would be obtained. Mention should be made of the self-cleaning card, the self-cleaner usually being either a special roller or a development of the fancy. In some cases these self-cleaners have undoubtedly been a success, but it is still questionable whether they constitute an improvement upon a fancy clothed with wire bent at the correct angle and properly speeded and set in relation to the swift. An important result of the better mechanical construction of the card is the marked increase in production, this in some cases amounting to an increase of at least 50%.

The carbonising process for freeing wool from vegetable matter usually subjects the material for a long time to a weak acid solution and then concentrates the liquor by drying. The more recent idea is to subject the wool for a very short time to a much stronger acid solution, a process which seems better suited to "cloth-carbonising" than to "wool-carbonising" as the material so treated is slightly yellowed. Perfect mechanical control is here necessary, the "time factor" being all important.

The best cotton opening and scutching machinery gives "the best cleaning power without damage to the fibres and the most regular lap-sheet with a minimum of labour." This ideal is

being attained by the better mechanical construction of opening, scutching and carding machinery. The mechanical advances made in connection with flax—a fibre often difficult to treat mechanically—may be mentioned. The flax-pulling machine is an accomplished fact and the automatic hackling machine is in use.

Valuable work has been done by the Research Assns. in the fields of physics and chemistry on the preparatory and other processes for wool, cotton, flax, silk, etc. Usually the revisions of processes advocated may be effected with the standard machines so that little mechanical revision has been called for.

**Combing.**—With reference to wool-combing, the French comb is being adopted by the wool industry very slowly, although almost universally used on the Continent and in Australia, due perhaps to present day "fashions" which do not call for the finer yarns. In the cotton trade, however, the Heilmann comb not only dominates but is step by step being improved in design. Thus, in Nasmith's improved Heilmann comb "reduction in wear and tear of the detaching roller surface" ensures much better combing results. It seems impossible to hope to treat flax-combing or dressing on any sort of really continuous line, but spun silk, which so far has been almost wholly prepared for drawing and spinning on the flax dressing-frame, is now being treated on the continuous system, although it is too early to say whether the results will be equal to those produced by the old method.

**Drawing and Spinning.**—In the wool industry machines of the intersecting gill-box type are being increasingly introduced. The details of the gilling and drawing boxes for wools are being more and more carefully worked out, even the electrical potentialities of the surfaces against which the slivers rub being carefully considered. Special reference should be made to the almost daily increase in the self-dippers in use in the worsted spinning industry.

In the cotton drawing-frame various devices have been tried to obtain better control of the comparatively short fibres between the drawing rollers, with some success, but the wear and tear of the various parts or additions are a serious consideration. In ring-spinning in the cotton industry the spindle-drive is in a state of transition and the adjustment of part to part has not yet been so satisfactorily solved that the machines may be said to be stabilised. On the other hand the mule may almost be said to have been evolved to a stable form. In wool spinning, perhaps the most notable change has been the tendency to adapt the ring-frame to fine wool spinning.

As to developments in the singeing of cotton yarns the gas flame has been more scientifically studied with the idea of producing the type of flame most suited to the purpose in view. The control of the thread and the intensity of treatment along with the getting away from the operatives of all the obnoxious products of combustion have also received most careful and successful consideration.

**Artificial Silk.**—The development of the artificial silk industry has drawn the attention of manufacturers to the winding or spooling process. So long as variations in tensioning did not markedly show in the cloth this process received scant attention, but now in most of the industries this matter is regarded as important and in the silk and "rayon" industry of dominant importance. The tensioning and winding of the yarn on to the spool or bobbin are now so successfully carried out that practically perfect pieces are produced, whereas previously very marked imperfections were observable.

**Weaving.**—The most noticeable attempt to improve the loom is the endeavour which has been made to throw the shuttle without either "over" or "under" picking arms. This has been successfully accomplished; the only question is—at what cost? The necessary strap and wheel connections in the new mechanism certainly bring the economies of the solution strongly to the front! Minor changes are producing an extraordinary difference in the fabric. The Northrop loom now meets the requirements of trades other than the plain cotton trade. Efforts to simplify looms and mechanisms for producing figured fabrics

are still being made, but so far without any outstanding success, although the Carver loom maintains its position in the linen industry.

**Finishing.**—The "scientific control" is steadily making headway. The "hydrogen-ion concentration" seems to be the passport in all fields of science at the present moment and although certain agents are known to promote the milling or felting of wool cloths, it has only recently been appreciated that a particular concentration of the bath is the dominant factor—less concentration and less milling but equally greater concentration and less milling! Then again the interesting series of British wools provided for the University of Leeds by the Royal Agricultural Society revealed in their milling properties variations of structure in the distinctive British wools which are leading to most remarkable deductions with reference to the fundamental structure of the wool fibre. This research bids fair to revolutionise some of the finishing processes which are daily becoming more scientific.

**Knitting and Knitting Machinery.**—Fascinating improvements in the possibilities of design and colour have been made, and flat-warp machines developed in which a texture is produced which bids fair to make a position for itself in men's wear markets.

**THAMES**, England (see 26.723).—A comprehensive scheme for the disposal of flood water was prepared in 1914, but proved too expensive. In 1921, however, a programme, involving an expenditure by the conservators of £290,000 over a period of seven years, was approved by Parliament. In the first two years £130,000 was spent on the improvement of weirs, locks, etc. The periodical Thames floods are not as formidable as they were, owing to the work of the Thames conservancy in dredging and enlarging weirs, but difficulties have arisen owing to the interference with natural drainage caused by the development of land in the Thames valley, the building of narrow bridges over tributary streams, the filling up of ditches, etc. The floods, such as those of 1925, are also rendered far more noticeable by the number of small houses erected on land subject to inundation. A large sum has been spent on dredging and new locks between Lechlade and Oxford, but there has been little increase in the traffic. A large double lock and transporters were opened at Boulton's Lock, Maidenhead, in 1912, and later the course was widened at Henley. A new lock has been built at Mapledurham. Locks, weirs and other improvements have been made at Iffley, and a lock (the largest on the river) and a boat conveyer at Teddington.

**The Thames Bridges.**—Much attention has also been given to the problem of the London bridges, and a committee of the London County Council was formed to inquire into the subject in 1924. The proposal to build a bridge at St. Paul's, authorised by Parliament, met with much opposition from the authorities of the cathedral. Proposals for the reconstruction of Lambeth bridge (closed to vehicles in 1910 in the interests of public safety), and for widening the Albert Embankment and Lambeth Road were in an advanced stage in 1924. Owing to subsidence, Waterloo bridge was closed in 1925 and a temporary bridge was erected alongside. The London County Council decided, despite opposition, to remove the old bridge and to build a new one of five spans and carrying six lines of traffic; a proposal to invite designs in competition was announced in March 1926. The bridge near Datchet has been demolished, and a new concrete bridge was in course of erection in 1925. A new bridge at Reading was opened in 1923, and the old one was being rebuilt in 1926. The question of a tunnel under the Thames to give further facilities for traffic between the east of England and the southeastern counties has also received attention. Estimates for its construction between Tilbury and Gravesend were prepared in 1924, and an engineering survey was undertaken in 1925. Precedence was given, however, to other road improvements nearer the centre of London. A scheme promoted by Sir Samuel Instone in 1924 for a fleet of motor boats on the river between Hammersmith and

Greenwich and Woolwich did not materialise, as the London County Council was not prepared to provide the necessary piers. In 1924 a company initiated a scheme for the construction of a wharf, a mile long, at West Thurrock, about 18 m. from London Bridge, to accommodate the largest vessels, with industrial development on modern lines of an area of 3,000 acres.

(O. J. R. H.)

**THAYER, ABBOTT HANDERSON** (1849–1921), American painter and naturalist (see 26.728), died at Dublin, N.H., May 29 1921. During the World War he worked in England on the development of camouflage.

**THAYER, WILLIAM ROSCOE** (1859–1923), American writer, was born in Boston, Mass., Jan. 16 1859. He studied at St. Mark's Academy, Concord, N. H., travelled with a private tutor in Europe, and graduated from Harvard in 1881. He was assistant editor of the Philadelphia *Evening Bulletin*, 1882–5 and then returned to Harvard, receiving the degree of A.M. in 1886. He was editor of the *Harvard Graduates' Magazine* 1892–1915. In 1903, at the International Historical Congress at Rome, he represented both Harvard University and the American Historical Assn., as also in 1906 at the Italian Historical Congress in Milan. He was a member of the Harvard board of overseers from 1913 to 1919. In 1918 he was elected president of the American Historical Association. He died at Cambridge, Mass., Sept. 7 1923.

Thayer was best known for his works on Italian history, especially *The Dawn of Italian Independence, 1814 to 1840*, 2 vol. (1893); *A Short History of Venice* (1905), and *The Life and Times of Cavour*, 2 vol. (1911). His other works include *Italica* (1908); *The Life and Letters of John Hay*, 2 vol. (1915); *Letters of John Holmes* (1917); *Theodore Roosevelt—An Intimate Biography* (1918); *Democracy: Discipline, Peace* (1919, lectures at Brown University); *Volleys from a Non-Combatant* (1919); *The Art of Biography* (1920, lectures at the University of Virginia); and *George Washington* (1922).

**THEATRE** (see 26.729).—The War period and the almost universal depression in trade that occurred shortly after had its effect upon theatre economics as upon nearly all other forms of business. The building of modern theatres virtually ceased in most parts of the world from 1914 to 1920, owing either to prohibition of what in England was termed luxury building or to commercially prohibitive cost resulting from the economic upheaval of the War. This cost has at least, if not more than, doubled; the expenditure on producing plays, *i.e.*, salaries of performers, wages of staff, prices of timber, canvas, materials and costumes, have risen similarly. Then taxation, both ordinary and upon entertainment receipts, has been an adverse factor. Increased rates upon property—an item that may run from £2,000 to £4,000 per annum or more upon an individual theatre—the outlay upon advertisements, travelling expenses of touring companies and other sundry expenses have all added to running costs, and, except perhaps in the United States of America, the result has been to limit development and experiment. The revenue obtainable has not generally been commensurate with increased costs. The public has paid from 75% to 200% more than before the War for many classes of commodities, but entertainment managers in England have found it impossible without endangering public patronage to raise admission prices to an extent comparable with the rise in expenditure.

On the continent of Europe—Germany, Austria and the Central States—the War produced even more serious economic results than in England or the United States. The worst effects have been experienced in Vienna, once a city of great theatrical and operatic activity. An impoverished and diminished nation could not support its luxury entertainments or those of a more educational character to the same extent as in pre-War days. Higher costs in every department necessitated higher prices of admission, to which was added special state and municipal taxation, with the result that except for a limited number of those who lived on capital or War time profits the great majority patronised what had formerly been the cheaper sections of theatre accommodation. The sum total of these factors resulted, more particularly in Central Europe, in the impoverishment of managers and the reduction of many artists to a state where it was

almost impossible to earn sufficient to provide themselves with the bare necessities of life.

#### COST OF CONSTRUCTION

The cost in 1914 of building and equipping a theatre in England capable of accommodating something between 800 to 1,200 persons was between £40,000 and £75,000, according to the locality and the degree of elaboration desired in architectural design, furnishing, decoration and equipment. A carefully prepared estimate of the cost of erecting a new theatre in the West End of London in 1925, consisting of ground floor and two tiers, to seat in all some 670 persons, showed this to be approximately £100,000, made up as to £30,000 for a freehold site and £70,000 for construction, furnishing, equipment and outgoings during construction. Upon this basis such a theatre when erected would involve an annual charge for interest on capital, local rates, depreciation of building, furnishing and equipment, cost of nucleus staff, heating, etc., approximating £12,500, or about £250 per week. In common with all other property, the rental values of existing theatres have tended to increase, although it is doubtful if generally the increase has been sufficient to compensate for the depreciation in the value of money.

Apart from the rise in prices of materials and wages since 1914, many other matters account for increases in constructional cost. Improvements in seating and in other details necessary to secure greater comfort have become essential and the municipal authorities responsible for the safety and health of the public have made demands necessitating substantial capital outlay. Exits are now required to have a better relation to the number of persons, whether performers or public. Improved arrangements of seating and gangways have been designed to diminish risk of injury or loss of life in fire or panic. Practical experience and investigation have resulted in regulations requiring better fire-resisting qualities of structural materials, scenery and hangings. Also it is only within comparatively recent years that scientific systems of heating and ventilation have been made compulsory by the licensing authorities and found desirable by owners of theatres. The most elaborate installations for these purposes cost from £2,000 upwards according to the size of the theatre.

Another factor in increased costs has been the invention and installation of elaborate systems of stage lighting and the use of high powered modern lamps undreamt-of in the early years of the century. From one stage switchboard all lights can be operated and different parts of the stage lit or put in shadow at will: the illuminative power can be easily diminished and changes of colour can be effected by the manipulation of a single switch. From a large switchboard hundreds of lights can be controlled by a single individual using the very simple mechanism.

#### IMPROVEMENTS IN DESIGN

In modern design the most important change, apart from simplification of decoration, has been the elimination of the boxes and all but one tier above the ground floor. In Great Britain the one tier principle is common in cinema theatres, but the most notable example up to the present time (1926) of a dramatic or variety theatre is the new Liverpool Empire, reopened in the autumn of 1925, which was designed and reconstructed at a cost of something over £160,000. This theatre is used for operatic, dramatic and variety entertainments of every kind. It has a sloped ground floor accommodating some 1,380 persons and one tier above accommodating about 1,100. There are no boxes and the rows of seats are so stepped in gradation as to give a good view of the stage from every point. Foyers, lounges, entrances and other conveniences are on a spacious scale. The stage is 100 ft. wide and 40 ft. deep, with a proscenium opening of 48 feet. Elaborate appliances for ventilation and heating as well as a hydraulic lift for moving scenery and properties from the street level to that of the stage above have been installed. As in many theatres nowadays, the stage and dressing room sections are fitted with sprinklers, from which floods of water can be released in case of fire. The system of stage lighting enables

elaborate changes and combinations of light and colour to be used by means of the footlights, the battens above the stage and the vertical lighting, the operation being easily and rapidly effected from the switchboard. In addition several powerful arc lights can be operated from above the tier to throw long beams of light of all colours to the stage.

Another important theatre reconstructed in 1922 is the Theatre Royal, Drury Lane, London. The old theatre had four tiers above the ground floor level and a large number of boxes. The new premises have only three tiers above the ground level and eight boxes on each side. The reconstruction of the interior cost approximately £150,000, and some idea of what is involved in modern theatre construction and equipment may be gained from the following facts. Every seat is of the tip-up armchair type, the theatre having a total seating accommodation for 2,300 persons. In the matter of heating and ventilation, the Plenum system has been adopted, *i.e.*, the air is drawn from the outside, washed and warmed to any desired temperature and then forced by a centrifugal fan through underground ducts to all parts of the auditorium. Suction sweeping plants electrically operated are used for cleaning the carpets, seating, etc. The auditorium has 400 separate light fittings, giving a total candle-power of over 60,000. The electric light, power, signal bells and telephone installations required some 15 m. of cable and 60,000 ft. of tube. On the stage an aggregate candle-power illumination of 40,000 can be obtained.

In Paris two new theatres have been constructed, both showing a great advance in regard to public comfort, heating and ventilation over the older type of Parisian theatre. One is the Théâtre de la Madeleine and the other the Théâtre de la Michodière. Both of these are theatres of the smaller type, appropriate for the intimate dramatic piece rather than for the large spectacular productions seen in theatres of greater dimensions.

*Employees.*—Persons employed in a theatre are represented as in other industries by trade unions or other associations. These organisations have secured increases in rates of pay for their members that are from 75% to 100% above the pre-War levels. The musicians by the Musicians' Union negotiate rates of pay for ordinary and overtime hours, rehearsals and other matters on behalf of their members. The stage and electrical workers and all those who are employed in the "front" of the house are represented in England by the National Association of Theatrical Employees.

In Great Britain the Stage Guild, a composite and important organisation of actors, managers and authors, has for its main objects the promotion, improvement and advancement of the interests and status of the theatrical profession in all its branches. The constitution of the guild contains a definite proviso against the imposing of any regulations or the adoption of any object which would make the guild a trade union. A trade union organisation, the Variety Artists' Federation, concerns itself with the conditions of contracts and other important matters affecting the welfare of variety artists, but many of these perform in what are technically stage plays, *e.g.*, the revues, in which members of the "legitimate" stage as well as of the variety are employed in London and the provinces.

In the United States the Actors' Equity Association is a powerful organisation which, after prolonged struggles, secured important conditions in the contracts of employment and other benefits for the advantage and protection of its members. Its authority is considerable.

Organisations representative of the employers now exist in most countries. These concern themselves with negotiations with the employees' organisations on questions affecting forms of contract, hours and conditions of labour, the fixing of a minimum wage and other matters of common interest, as well as with legislation affecting either the capital or labour employed in the entertainment industry.

#### PRODUCING AND RUNNING COSTS

In Great Britain the cost of producing a non-musical play for a medium sized theatre—that is to say, the scenery, costumes, prop-

erties, rehearsals, salaries and wages—may be put at between £1,000 and £2,000. The corresponding cost for musical comedies and revues may run from £5,000 to £15,000. The expenditure per week for running a non-musical play would be from £800 to £1,200. This expenditure would cover salaries of actors, stage staff (including carpenters, electricians and others) management, accountancy, box-office, check-takers and other persons employed in the "front" of the house; advertising and printing; lighting, heating and sundry expenses and authors' royalties (generally a percentage of the receipts).

The surplus of receipts over weekly running expenses must first be devoted to paying off the production expenses. If the run of the play continues long enough for this to be done then profits may be made; if the run is short, as often happens, the production cost may wholly or partly be lost. If to the running costs mentioned above be added the weekly fixed charges for rent, rates, repairs, depreciation and "front" of house staff, it will be seen that the cost of running a theatre with an average non-musical play may be from £950 to £1,500 or more per week. The revenue capacity would be about £200 to £250 per performance or £1,400 to £2,000 (according to the size of theatre) per week, inclusive, of supplemental income from bars, etc. In the larger theatres and for musical comedies or revues, expenditure may run from £2,000 to £2,500 or more per week; the receipts from an outstanding success may in such cases be from £2,500 to £5,000 or more weekly, according to the holding capacity of the theatre and the number of performances given.

Theatrical enterprises are very susceptible to temporary adverse causes, *e.g.*, inclement weather in winter time; great heat in summer; industrial upheavals and crises, sickness of the leading actors engaged, and any of these factors may—unless, which is unusual, large capital resources are available to tide over a bad period—determine the fate of a play irrespective of its merit. Experience has shown, too, that a large proportion of failures are unavoidable and substantial profits are required to secure over a period of years a reasonable degree of stability and of financial success.

The entire financial liability of maintaining and running a theatre is rarely undertaken in England by a single individual or company. The theatre owner or lessee may let his theatre for a fixed weekly or annual sum, and beyond sometimes an approval of the plays to be produced has no concern with the presentation of the plays. More commonly, however, the theatre-owner enters into a sharing arrangement—in effect, a kind of partnership with the producer of the plays. In turn the producer often forms his own company or syndicate for the financing of his participation in the arrangement. Receipts are shared upon an agreed basis, the producer paying out of his share for everything seen and heard upon the stage, and sometimes a proportion of other agreed outgoings such as advertising. The lessee or owner pays all fixed expenses such as rent, rates, taxes, as well as for the staff and organisation of the "front of the house." Such an arrangement is usually determinable at the end of a fixed period, or when the receipts fall below a certain sum for an agreed minimum number of weeks.

From the foregoing it will be seen that the successful theatre owner, manager or lessee must be a capable man of business. He should also possess imagination, and something more than a casual knowledge of the technical and artistic side of the theatre. He must be familiar with theatre design and equipment, structure and maintenance; he should similarly be capable of forming a judgment of plays, of actors and the taste of the public. In the opinion of some people a division of the business from the artistic side is considered desirable to secure the best results, but as a rule a clear division is not to be found. Generally, close co-operation, sympathy and understanding of all the factors by all those engaged in a theatre organisation are essential. Vital as is the literary side of the theatre, important as are the scenic and costume design and the art of the actor and of the producer or stage director, the development of the theatre as an institution and its success commercially as well as in public estimation must in the long run depend, not upon isolated triumphs of great artis-

tic effort financially unsuccessful, but upon a wholesome respect for the well laid and hard foundation stones of economic facts and law. (W. P.)

**THEOLOGY** (see 26.772).—It will be convenient to preface this review of theological development with a reference to the Modernist movement in the Roman Catholic Church which was active during the opening years of the present century, for this movement throws into relief tendencies of thought which have remained operative down to the present.

*Roman Catholic Modernism 1902-7.*—It was the aim of Roman Catholic Modernism to bring the theology of the Church into relation with the thought of the modern world by means of a new theological method which would enable Roman Catholic scholars to move freely in the modern study of nature and of history, especially Biblical and ecclesiastical history, while remaining loyal to the dogmatic affirmations of the Church. It was urged, e.g., by M. Le Roy, a distinguished representative of the school of Bergson and Boutroux—that the *impasse*, in which Catholic apologetic now found itself, was due to the assumption on the part of friends and foes alike that the primary meaning of dogma was intellectual and that its practical and moral meaning was derived from its intellectual meaning. This assumption rendered the entire conception of authoritative dogma impossible to the modern mind. The true policy in religious apologetic was to revise the conception of dogma and to recognise that from an intellectual point of view the function of dogma was negative only: the positive function of dogma was only relevant to the world of conduct and behaviour.

A similar philosophy underlies Loisy's famous criticism of Harnack. Harnack's attempt to treat faith in the Fatherhood of God as the immutable essence of the Gospel is a piece of unconscious scholasticism. The teaching of Jesus was itself conditioned by the eschatological expectation, and from the very beginning the Church has adapted the Gospel to the ever changing conditions of human life. The intellectual or logical development recognised by Catholic theology does not cover the facts. "It is the notion of 'development' itself that we now need to develop."

By the Papal Encyclical *Pascendi dominici gregis* of Sept. 1907 the Vatican disallowed the new apologetic, and the Roman Catholic clergy is required to accept the main positions of the scholastic theology: the existence of God provable by the natural light of reason, revelation attested by miracles and prophecies, the Church founded by Jesus Christ upon Peter and his successors forever, the apostolic doctrine transmitted unchanged through the orthodox Fathers to ourselves, faith the true assent of the intellect to truth revealed from without.

The Modernist movement in the Roman Church coincided with fresh developments in non-Roman theology. Two forces, both ultimately deriving from the Romantic movement of a hundred years ago may be first distinguished (1) the historical and comparative study of religion, (2) the psychological study of religion.

#### THE HISTORICAL AND COMPARATIVE STUDY OF RELIGION

*Comparative Study of Religion and Systematic Theology.*—The school of Ritschl, which on the whole had remained the most important theological influence in Germany until towards the close of the 19th century, had confidently appealed to the prophetic religion of the Bible, had assumed the immediate relevance of the teaching of Jesus upon the kingdom of God, and had decidedly depreciated non-Biblical religions, and non-Biblical elements in Christianity. The *Religionsgeschichtliche Methode* has led to a change in emphasis: (a) Wider acquaintance with the background both of the Old Testament and of the New Testament has brought into prominence the relation of the Biblical documents to the external conditions which helped to determine their form and content. (b) There is a general disposition to recognise a genuine eschatological element in the preaching of the historical Jesus, which had been slurred over by many "Liberal" theologians. (c) Further study of the religious history of mankind has revealed the inadequacy of

Ritschl's unsympathetic attitude towards non-Biblical religions. We may here note that some of the earlier New Testament studies of the *religionsgeschichtliche Schule* tended to regard primitive Christianity as essentially syncretic; but, while the new criticism has left a permanent mark upon the study of Christian origins, later work shows a fresh grasp of the distinctive position of Christianity in history.

*Troeltsch's Work.*—Valuable suggestions towards a new dogmatic have been made by Troeltsch. Troeltsch follows Schleiermacher in his fundamental idea of dogmatic. Dogmatic presupposes and depends upon scientific studies, but it is not itself a science. Its proper aim is the instruction and edification of the religious community. A Christian dogmatic orientated in view of the historical study of religion must first form an estimate of Christianity in relation to other world faiths. Secondly it must form a conception of the "essence" (*das Wesen*) of Christianity. Thirdly dogmatic consists specifically of the presentation of this "essence" of the Christian Faith. Uncertainties consequent upon historical criticism make it unsatisfactory to propose historic personalities as *direct* objects of faith: present experience with its metaphysical implications must give us our direct approach to God. But historical personalities—especially Jesus—are essential as "sources of power" and "points of concentration," without which a religious community cannot exist. Thus dogmatic will fall into two parts:—(a) A valuation and interpretation of the historical personalities for the individual and for the community. (b) A presentation of the metaphysico-religious conceptions of Christian thought about God, the world, the soul, redemption, the religious fellowship, the last things.

#### THE PSYCHOLOGICAL STUDY OF RELIGION

The Romantic Movement, represented for Theology by Schleiermacher, conceived of religion as a state of feeling rather than as a system of beliefs. The psychological interest in religion thus aroused has persisted and has led to important works on religious psychology during the period under review. Much recent apologetic, encouraged by psychologists such as William James, tends to base itself upon the authority of "religious experience." Writers upon the psychology of religion recognise in general that the science of psychology as such is not concerned with the validity or invalidity of religious beliefs. Leuba however has not only criticised James' wish "to believe in a mystical revelation," but has claimed "to have shown that the truth-kernel of religious ecstasy is no other than the truth-kernel of narcotic intoxication, and of ecstatic trance in general." Other psychologists, influenced by psycho-pathological theories of projection have argued that religion is to be explained in terms of hallucinatory images formed by the mind, to which objective reality is wrongly ascribed.

*Otto's Theory.*—Otto's theory of "the holy" more directly concerns dogmatic theology. Otto follows Schleiermacher in regarding religion as fundamentally a "feeling of dependence" but he criticises Schleiermacher for not recognising the unique quality of the feeling of dependence in religion, which may be expressed through the term "creature-feeling"; and secondly, he criticises Schleiermacher for making belief in God an *inference* from the feeling of dependence whereas, according to Otto, the creature-feeling carries an immediate reference to an object outside the self. The object is "the holy," or, as Otto prefers to call it, "the numinous." "The holy" is an ultimate category of thought, presupposed in all religious experience, and is to be distinguished alike from the "rational" and the "moral."

#### PHILOSOPHICAL THEOLOGY

We conclude with a reference to developments in philosophical theology. There has been a reaction from the Ritschlian attempt to sever metaphysics and religion. Troeltsch, as we have already seen, aimed at a correlation of theology and philosophy. Ritschl has never dominated British theology. During the latter part of the 19th century the British Hegelians kept interest in philosophical speculation alive in Britain after the idealist movement had died down in Germany, and they exercised wide

influence on theological thought. They have left both disciples and dissenters who have made important contributions to philosophical theology. Of especial importance to theologians are Rashdall's and Sorley's arguments for Theism on the basis of the moral consciousness. Mention should also be made of Professor James Ward's development of a theistic position from a pluralistic starting point.

Finally we may allude to the rise of a new school of theology in Germany led by Karl Barth. This school starts from Paulinism and the conception of faith, and aims at emancipating theology from the psychological subjectivism and historical relativity which have hampered it since the rise of the Romantic movement, and at restoring the sense of objective spiritual reality.

Lloyd Morgan, *Emergent Evolution* (1923). (J. M. Cr.)

**THERAPEUTICS** (see 26.793).—Since 1910 very considerable changes have taken place in our knowledge, and our general conception of the problems involved has been correspondingly broadened.

**Prevention.**—Prevention, the ideal aim of medicine, has greatly advanced in its practical application (in this country this has been fostered by the establishment of a Ministry of Health in 1919 which has greatly expanded the scope of work carried on by the Local Government Board, and also by the activities of the Medical Research Council founded in 1913 as part of the National Insurance Scheme). Preventive medicine includes, in addition to improvement of environmental conditions, prophylactic treatment in the very early stages of disease, such as can be provided in antenatal, school, dental and venereal clinics and so comes within the number of advances to be chronicled under the heading of therapeutics.

A notable example of prophylactic treatment is the prevention of goitre (see GOITRE) or, as in this country it is often called, Derbyshire neck; this is an endemic or local disease, probably depending, as Lieut.-Colonel R. McCarrison in India showed, on contamination of the water supply with micro-organisms; it is extremely prevalent in Switzerland and in North America both

in men and lower animals in the neighbourhood of the Great Lakes, and has been found to be associated with a diminished content of iodine, which has a well-marked antiseptic action, in the thyroid gland. By the periodical administration of iodine to children in districts where the condition is prevalent it has been most successfully prevented.

**Deficiency Diseases.**—Another aspect of the same question is presented by the group of "the deficiency diseases" or the avitaminoses, which depend on the absence from the food of the vitamins or "accessory food factors." As constituents of food these vitamins (*q.v.*), of which there are several, are remarkable for the contrast between the extremely minute amounts present and the striking changes resulting from their absence. Their chemical constitution is unknown, but they are mainly formed in vegetables and plants, including yeast, and pass into herbivorous animals and so are available for those whose diet is confined to meat. Their absence from the diet stops growth and causes certain diseases, such as beri-beri (see BERI-BERI) a disease of the nerves due to a diet of polished rice from which the husk containing the water-soluble B vitamin has been removed; if a man or animal suffering from beri-beri is given the rice polishings of the husks the disease disappears.

Scurvy (see TROPICAL MEDICINE), formerly a serious disease in the navy in long voyages, was banished just before the close of the 18th century by the empirical use of fresh vegetables and fruit juices, but recurred in the armies in certain areas during the World War, due to the absence of a vitamin named water-soluble C. Infantile scurvy is sometimes seen in civil life in babies fed most carefully but too exclusively on boiled milk.

Rickets is due to deficiency of a fat-soluble vitamin (D); this antirachitic factor can be produced by the action of sunlight and ultra-violet rays on a large number of foodstuffs, especially fats, and from cholesterol. Another probable deficiency disease is pellagra, due to eating maize and a diet defective in protein (*e.g.*, meat).

**Tropical Diseases.**—The prevention of tropical disease originated in Great Britain under Sir Ronald Ross's direction with the destruction of the mosquito, the carrier of the malarial parasite (see TROPICAL MEDICINE), has been much expanded by the Rockefeller Foundation, which has instituted many campaigns against diseases, such as malaria, yellow fever and especially a world-wide attack on ankylostomiasis, a disease due to a worm in the intestines (see HOOKWORM; MALARIA; YELLOW FEVER). Yellow fever, which formerly took such a terrible toll of life, has now been almost entirely eradicated from South America by destruction of mosquitoes, the carriers of the infection.

**Inoculation.**—The World War proved the enormous value of prophylactic or protective inoculations against certain diseases on the same lines as Edward Jenner's vaccination against small-pox (*q.v.*). Just before the South African campaign Sir Almroth Wright started the method of protection against typhoid fever (see IMMUNITY) by injection with a vaccine composed of killed cultures of the *Bacillus typhosus*; this inoculation sets up changes in the body which render the individual immune for a time, probably about four years, to this form of infection, in the same way as an attack of the disease. After the South African campaign cases were observed resembling typhoid fever but due to different though allied bacilli, and two additional forms, paratyphoid A. and paratyphoid B., of fever became recognised, the three diseases being collectively described as enteric fever (see INFECTIOUS FEVERS). In order to protect against infection of these three forms of fever, it is necessary to inoculate the individual with the three vaccines, and soon after the outbreak of the World War paratyphoid fever attacked the troops in Flanders and did not spare those inoculated against typhoid fever only; the three vaccines, known collectively as T.A.B., were then given, and the wonderful freedom of the army from enteric fever, which in past wars has killed as many as bullets, is a triumph for preventive medicine. In a like manner men who were wounded and so likely to be infected with *Bacillus tetani* (see TETANUS), which appeared to be common in the much cultivated Belgian soil, were at once injected with the antitetanic serum and so protected from tetanus or lockjaw.

Dysentery (*see* DYSENTERY) is another war disease, and there were many cases among the troops at Gallipoli and elsewhere in the East. There is more than one kind of dysentery. One of them, amoebic dysentery, is prone to be followed by liver abscess, the amoeba passing to the liver. Before the War it was found that emetine, an alkaloid of ipecacuanha long known as an empirical remedy for dysentery, was extremely efficient in curing this form of dysentery and also the hepatitis or inflammation of the liver which precedes the formation of an abscess. Our soldiers suffering from dysentery were injected almost as a routine with emetine and the number of cases going on to liver abscesses was surprisingly few. The other common form of dysentery due to a bacillus was treated with an antidysenteric serum, but not with such success.

As a result of the large numbers of officers and men who suffered from war strain and its effects, often called shell-shock, during and after the War, the psychotherapy (*see* PSYCHOTHERAPY) of these nervous disorders has greatly developed.

**Endocrine Therapy.**—When any of the endocrine glands, the thyroid, adrenals, pituitary, which pour an internal secretion into the blood and keep the body in health, are diseased or fail to do their work properly, signs of disorder or disease result. The secretion may be suppressed or diminished, excessive or altered in character (*see* ENDOCRINOLOGY). When the secretion is diminished an attempt to provide it can be made, and in the case of thyroid, which when inadequate produces myxoedema, or in early life cretinism, brilliant results have long been obtained by this substitution therapy or giving the thyroid gland or an extract of it by the mouth. In 1914 E. C. Kendall of the Mayo Clinic, Rochester, Minnesota, obtained in a pure form the active principle—thyroxin—which is extremely effective. The parathyroid glands, small bodies close to the thyroid gland in the neck, manufacture an internal secretion which passes into the blood and exerts an action apparently opposed to that of the thyroid. Whereas the thyroid is concerned with the control of iodine in the body, the parathyroids deal in a similar manner with calcium salts. Deficiency in the action of the parathyroids appears to lead to a diminished quantity of calcium salts in the body and to an irritable state of the nervous system, and is thought to be responsible in children for the contracture of the hands and feet known as tetany, though on this question there is considerable discussion. Recently the extract of the parathyroid glands has been given in a number of diseases of a chronic infective nature, especially in sprue (*see* SPRUE), a tropical disease characterised by diarrhoea, want of digestion of food so that the patient wastes as if from starvation. It has also been recommended for ulcers slow to heal and other obstinate conditions.

**Organo-therapy.**—An outstanding advance on organo-therapy is the insulin treatment of diabetes mellitus (*see* DIABETES). In this disease the patient, who is unable to utilise sugar and starches, passes sugar in the urine, wastes and may eventually die in coma. The pancreas, or sweetbread, is a gland concerned with the digestion of food, including starches, in the alimentary canal, and at the same time that it provides this external secretion pours an internal secretion into the blood which enables the body to make use of sugar. This internal secretion is manufactured by structures in the pancreas known as the islands of Langerhans, and the extract from them is called insulin. After many trials the technical difficulties in obtaining a satisfactory insulin (*see* INSULIN) were surmounted in 1922 by F. C. Banting and C. H. Best of Toronto, and a remedy was thus made available, which though it does not cure diabetes, any more than thyroid extract cures myxoedema, yet for some hours makes the previous diabetic practically a normal person as regards the utilisation of starch and sugar. The hypodermic administration of insulin must be repeated at least once daily, but this treatment keeps the disease in abeyance and has thus prolonged and saved innumerable lives. In diabetes insipidus, a comparatively rare disease, in which large quantities of urine free from sugar are passed, relief for some hours is similarly obtained by hypodermic injection of extract of the posterior lobe of the pituitary gland. The success of thyroid and insulin treatment has stimulated

research and trial in the case of other glands and numerous commercial preparations have been placed on the market; but the claims sometimes made for various forms of organo-therapy have yet to be confirmed.

**Chemiotherapy.**—Chemiotherapy, or the use of a drug which has a selective affinity for a germ and leads to its destruction without damaging the tissues of the body, was the conception of Paul Ehrlich of Frankfort-on-Main who in 1910 discovered the specific remedy "606" or salvarsan which rapidly leads to the destruction of the *Spirochaeta pallida* (*see* VENEREAL DISEASES), the protozoan responsible for syphilis. It now appears that the action is not independent of the activities of the patients' bodies and that the germ is not poisoned and killed off solely by the drug, which indeed may damage the tissues of the patient very severely and even cause death, so that the ideal of chemiotherapy has not been realised. Remedies of this class are, like quinine in malaria, specific, lead to a complete cure, and are therefore of the greatest importance in opening a new vista in medicine. Since its introduction salvarsan and its modification neo-salvarsan "914" and allied organic preparations of arsenic have been increasingly used in the numerous results of syphilis with great success; but this treatment has its limitations, for when the parasite of syphilis gets inside the central nervous system and causes locomotor ataxia and general paralysis of the insane the drug cannot follow the spirochaete and the disease is little if at all influenced. Recently it has been found that inoculation with the malarial organism and an attack of the disease benefits patients with general paralysis, but how far this is a permanent cure remains to be proved (*see* MALARIA). Trypanosomes, animal (or protozoan) parasites closely akin to spirochaetes are responsible for diseases, such as trypanosomiasis and African sleeping sickness (to be distinguished from quite a different disease epidemic to encephalitis [*see* ENCEPHALITIS LETHARGICA] popularly called sleepy sickness) which are also curable by the organic arsenical compounds atoxyl and arsacetin. Tartar emetic, a salt of antimony, acts like arsenic on trypanosomes and in addition effects a cure in bilharziasis (*see* BILHARZIASIS) (a disease due to flukes), filarial disease and kala-azar, three tropical infections (*see* KALA-AZAR; PHARMACOLOGY).

**Serum Therapy.**—Just as in enteric fever, so in cerebro-spinal ("spotted") fever and pneumonia (*see* CEREBRO-SPINAL FEVER) bacteriology (*q.v.*) has shown the existence of several strains or types of the causal micro-organism; these though morphologically indistinguishable are so biologically different that each is most efficiently treated by an antitoxic serum, obtained from an animal injected with, and so immunised to, that particular type. Before the recognition of these types antitoxic serums were employed, but they might or might not correspond to the exact strain of the micro-organism present in an individual case. In 1913 Douchez and Gillespie, working at the Rockefeller Institute, New York, isolated four types of pneumococci, the micro-organism causing acute pneumonia; but it is only the antitoxic serum corresponding to pneumococcus type I that is curative.

During the War, especially in 1915, epidemic cerebro-spinal meningitis or cerebro-spinal ("spotted") fever became prevalent among the fighting forces, especially in young recruits. It is due to the *Meningococcus intracellularis* (*see* SERUM THERAPY), and in order effectively to neutralise its effects Simon Flexner of the Rockefeller Institute prepared an antitoxic serum from animals immunised from 40 different strains (multivalent). This serum is injected by lumbar puncture into the (subdural) space around the spinal cord, so that it can come into direct contact with the meningococci which chiefly select the central nervous system. The prevalence of the disease stimulated research and strains of meningococci were isolated; Mervyn Gordon, working for the Medical Research Committee (now Council) which devoted all its energies with great effect to the conditions of diseases in the troops, isolated four types of meningococci and prepared four corresponding mono-type sera; when a case was bacteriologically proved to be due to infection with one of these strains, the corresponding serum was given; while waiting for the bacteriological decision as to the responsible type, a mixture of

type I and type II serum was given, as 80 to 85% of the cases were due to these strains.

**Tuberculosis.**—The search for a specific remedy for tuberculosis, such as a new form of tuberculin, an antitoxic serum or a metallic preparation analogous to salvarsan or tartrate of antimony in protozoan diseases, has continued, but no finality has been reached (see TUBERCULOSIS). Spahlinger's treatment by vaccines and serums has received intermittent attention, mainly in the lay press; Dreyer in 1923, by removing the fatty material from tubercle bacilli, obtained a vaccine, called diaphyte, which has been tried on human beings, and from experiments on animals was at first thought to have an increased effect, as compared with other vaccines; later reports have not been favourable, but both experimentally and clinically it may still be premature to decide about its ultimate value. Quite recently sanocrysine (a gold compound) has been introduced by Möllgaard of Copenhagen and is at present on trial; it is a powerful remedy which kills the tubercle bacilli and, by liberating their poisons, may produce severe constitutional reactions; Knud Faber, from his clinical experience, points out that in order to avoid these dangerous results, the doses should be small.

In pulmonary tuberculosis a great factor in obtaining arrest and cure of the disease is rest, and in order to immobilise the lung the production of artificial pneumothorax (*q.v.*) is now widely practised. Air is introduced into the pleura—the space between the lung and the chest wall—on the other side of the affected lung which then collapses and comes to rest, all the work of respiration being carried on by the other lung. This procedure has given very good results in selected cases. Treatment in sanatoria is of great value in arresting the progress of pulmonary disease and in teaching the patient the laws of health that he must follow, but it is now becoming recognised that there is urgent need for a more prolonged protection from the strain of ordinary life in the environment of cities, and that tuberculous colonies in the country are required for this purpose, such as Papworth near Cambridge and Preston Hall near Maidstone.

The treatment of leprosy (see LEPROSY) by intravenous and intramuscular injections of soluble products of chaulmoogra, hydnocarpus, soya bean and cod-liver oils, as advocated by Sir Leonard Rogers, has been shown by reports from leper asylums in various parts of the world to have had beneficial effects and to have reduced the death-rate in a remarkable manner. Although there are very few lepers in this country, there are 300,000 in the Empire, and at a conservative estimate 1,700,000 in the world, so that any efficient remedy is obviously important.

**Protein Therapy.**—By a turn of the wheel the strictly scientific employment of vaccines composed of the micro-organisms thought to be responsible for the morbid condition has led by an empirical process to non-specific protein therapy. It was found, sometimes accidentally, not only that the administration of a vaccine specific for one form of infection benefits a morbid condition due to another infection, but that intravenous injection of foreign protein, such as peptone and milk, may when they set up a reaction, namely fever, shivering and illness, ("protein shock therapy"), produce a beneficial effect, just as one disease sometimes cures another. This protein shock therapy has been employed particularly in asthma and in chronic rheumatoid arthritis.

After an attack of many infective diseases there develops an immunity so that a second attack is rare; the reverse of immunity is an exaggerated susceptibility or hypersensitiveness; this is what is meant by idiosyncrasies and the proverb "What is one man's meat is another man's poison." This is seen in various diseases, such as recurrent colds and asthma. A method of cure is to desensitise the subject of one of these toxic idiopathies by the administration, usually by hypodermic injection, of the substance, a bacterial or other protein, to which the individual is hypersensitive. Thus a patient subject to hay fever is injected with the pollen of the plant which excites an attack; or a patient with bronchitis and asthmatic seizures is injected with an emulsion of dead bacilli (vaccine) obtained from the expectoration.

In many cases of disease and ill-health the cause is a "septic

focus" or a local collection of micro-organisms, for example, in the teeth (see DENTISTRY), tonsils, appendix, gall bladder and intestines, which poison the body and may produce chronic painful conditions, such as chronic arthritis, sciatica, lumbago, fibrositis. The removal of such foci is therefore the important and indeed the first step in treatment; after that vaccines made from the predominant micro-organism present in the focus, and spa treatment may complete the cure.

**Anaemia.**—The fatal form of anaemia (*q.v.*) called pernicious or Addisonian after its describer Thomas Addison of Guy's Hospital (see ANAEMIA) is the result of chronic infection of the stomach and alimentary canal, which in its turn may be due to a septic focus, but it now appears from the observations of Arthur F. Hurst, also of Guy's Hospital, that an important factor is absence of the hydrochloric acid in the gastric juice which enables the micro-organisms causing pernicious anaemia to take root and live instead of being, as in normal people, destroyed. It has, therefore, been treated by supplying the absent hydrochloric acid by its medicinal administration by the mouth, with a success which is due to investigation of the chemistry of the stomach.

In this, as in anaemia due to haemorrhage, the operative procedure of transfusion of blood (see BLOOD TRANSFUSION) has been carried out, after the blood of the donor has been compared with that of the patient to see that they are compatible and after measures have been taken to avoid transmitting diseases, such as influenza, malaria and syphilis from the donor. Transfusion of blood is a very old method of treatment and was performed as long ago as 1667, but it is only recently that the tests for the compatibility of the blood based on the existence of four blood groups in man have rendered the procedure less dangerous. Transfusion of blood with these precautions was employed on a large scale in the War for haemorrhages and severe shock, as from gunshot and shell wounds, and has also been used in conditions popularly called blood poisoning. A recent development of blood transfusion is to immunise by means of vaccines, made from the micro-organism infecting the patient, the blood of the donor, and then to transfuse his blood into the patient.

**Radiotherapy.**—X-rays, though mainly employed for diagnosis, have from their power of destroying the tissue cells, many therapeutic uses. Thus enlarged glands and the spleen in various diseases of the blood, and especially in lymphadenoma, are much reduced by X-ray exposure. The recent Erlanger treatment of internal cancer by intensive X-rays has the grave disadvantage of making some patients extremely ill (see RADIO THERAPY). Radium bromide, the rays of which are much the same, has been much used in the treatment of inoperable carcinoma and, in quite superficial growths of the skin, especially rodent ulcer on the face, which, though classed as malignant, is much less virulent. In cancer of the uterus radium has proved of unquestionable value; from a combination of operation and radium good results have been obtained in cancer of the breast; but in malignant growths of the tongue, mouth and throat its use has generally been disappointing. Gye and Barnard's discovery of the long sought parasite of cancer brings nearer the possibility of obtaining a cure, by a vaccine or a serum. (See CANCER and MICROSCOPY.)

The important advance in the diagnosis of disorders of the heart and the mechanism of its beat have been followed by a more accurate knowledge of how to give digitalis and by the employment of quinidine in the disorders known as auricular fibrillation and paroxysmal tachycardia. Numerous researches have been undertaken with the view of devising reliable tests for the functional activity of the liver, and it is clear that sugar is the food which most readily protects and repairs the damaged liver cells.

**Heliotherapy.**—Recent years have shown an increasing tendency to utilise to the full the *vis medicatrix naturae* in open air treatment, improved ventilation, heliotherapy which has indeed been imitated by the use of ultra-violet rays (see HELIO THERAPY), baths and waters, and exercises. The prophylactic measures based on experience and empirical use have been elaborated by the teaching of scientific research and as a result physiotherapy

or physical therapeutics, which includes massage and the various forms of electrical treatment, has considerably advanced in knowledge and application. Medical hydrology has been studied and taught on these rather than on purely empirical lines, and it may be noted that spas did excellent work during and after the War for invalided soldiers. Hand in hand with open air treatment and heliotherapy has come less surgical activity in the way of operating in tuberculous disease of bones and joints.

(H. Ro.)

**THERMIT** (see 28.501).—Thermit is a mixture of aluminium powder and iron oxide. On ignition the reaction,  $8\text{Al} + 3\text{Fe}_3\text{O}_4 = 9\text{Fe} + 4\text{Al}_2\text{O}_3$ , gives a temperature estimated to be between  $2,300^\circ$  and  $2,700^\circ$  Centigrade. The reaction, stated in weights, means that 217 parts of aluminium plus 732 parts magnetite (iron oxide) equals 540 parts steel plus 409 parts slag, or approximately, three parts of aluminium plus 10 parts of magnetite will produce, on combustion, seven parts of steel. This steel represents about one-half of the original thermit by weight and one-third by volume.

**Discovery.**—Thermit was discovered by Dr. Hans Goldschmidt, of Essen, Germany, in 1895, while trying to reduce chromium and manganese. Dr. Goldschmidt's principal discovery related to a simple and safe method of ignition, as the action of aluminium when mixed with various oxides, sulphides and chlorides was well known. Fine aluminium will not burn below the temperature of molten cast iron, and previous experimenters had resorted to heating their mixtures in a crucible. This made the initial temperature so high at the moment of ignition that there was an explosion. Dr. Goldschmidt obtained ignition of a cold mixture by means of a barium-peroxide fuse, which was set off by a storm match. Later, magnesium powder or ribbon was used, being set off in the same way. A red-hot iron rod may also be used to set off the magnesium, which in turn ignites the thermit. Dr. Goldschmidt's original American patent No. 615700 was granted March 16 1897 and related principally to the use of aluminium as a reducing agent for the production of carbon-free metals such as cobalt, chromium, magnesium, tungsten, etc., by what is now known as the aluminothermic process. Thermit is now used considerably in the foundry for purifying iron and steel in the ladle. For this purpose the thermit is placed in a can on the end of a rod and plunged to the bottom of the molten metal. The intense heat generated tends to liberate many impurities which are carried away in the slag. The principal and better-known use, however, is in welding.

**Thermit Welding.**—Two methods are employed, known as the plastic and the fusion. The first is used for welding pipe and the latter for solid or large sections. In the plastic method, in which the thermit is used merely for heating purposes, the ends of two pieces of pipe are machined square and clamped in a cast-iron mould with the ends butted together. This mould is in two parts, so arranged that the pipe ends may be forced together when heated. The thermit is placed in an open-top crucible lined with magnesia-tar, and ignited. After the reaction takes place, the slag, which is of course lighter in weight, rises to the top of the molten metal, and is first poured into the mould. This slag forms a protective coating on the pipe and on the inside of the mould, and keeps the thermit from melting or burning through. At the right the thermit is shown flowing into the mould and forcing out the bulk of the slag, but leaving a coating as mentioned. When the pipe ends become plastic they are forced together, completing the weld. After cooling, the mould is easily knocked off, since the slag coating prevents adhesion. To weld a pipe takes from  $\frac{3}{4}$  to  $1\frac{1}{2}$  minutes.

In fusion welding on solid sections, in which the thermit mixture forms a casting holding the parts together, a special V-shaped magnesia-tar-lined crucible, open at the bottom, is used. The hole in the bottom is closed by a headed plug, covered with refractory sand, which may be pushed upward. This crucible is placed over the mould, the proper amount of thermit put in and ignited. After the reaction, which takes about 35 sec., the plug in the bottom is pushed up and the molten thermit allowed to run into the mould. In this method great care is taken to keep

the slag from contact with the surfaces to be welded, and in consequence of this the amount of thermit which is used must be sufficient to fill the mould before the slag on the top of the melted metal can enter. In welding, the surfaces to be joined should be cut or set so as to be  $\frac{1}{2}$  in. or more apart. Yellow wax is then built up around the joint in the same shape as the weld is to be.

Next the mould box is placed and sand rammed up round the wax, wooden patterns being placed for the pouring gate, riser and preheating gate. The mould is vented, the patterns withdrawn and a gas or oil flame used to melt out the wax. The heating is continued until the sections to be welded are red-hot. This prevents, as is necessary, the thermit from becoming chilled. The next step is to pour in the thermit, but this must be after the preheating gate has been plugged. Some of the principal uses to which thermit is put is in repairing broken rudder frames, propeller shafts, locomotive frames, steel rolling-mill pinions and other heavy sections, but it cannot be economically used for welding thin sheet metal sections. Welds have been made where from 3,000 to 4,000 lb. of thermit were used. For commercial purposes there are now produced three varieties of thermit, known as plain thermit, railroad thermit and cast-iron thermit. The plain thermit is simply a mixture of aluminium and iron oxide, as already given. Railroad thermit is plain thermit with the addition of  $\frac{3}{8}\%$  nickel, 1% manganese and 15% mild steel punchings. Cast-iron thermit is plain thermit with the addition of 3% ferrosilicon and 20% mild steel punchings. The names of these mixtures indicate their principal uses. (E. Vr.)

**THERMODYNAMICS:** see HEAT.

**THERMO-ELECTRIC PYROMETER.**—The thermo-electric pyrometer is most generally used for measurements of high temperatures in industry, such as the temperatures of furnaces of all kinds as, for example, for annealing, hardening, tempering, carbonising or case-hardening; blast furnaces; the temperatures of molten metals; the temperatures in galvanising, tinning, lead and salt baths; the temperatures in various processes in brick, tile, pottery and glass works, and the many temperatures throughout an efficiently operated boiler-plant. The pyrometer is also used to determine the recalcence points of steel, the freezing points of alloys and in connection with general research work in the laboratory.

**General Principles.**—If two wires of dissimilar metals are joined at their ends to form an electric couple, and one junction is heated, an electromotive force is set up which gives rise to an electric current in the circuit. The magnitude of the electromotive force depends upon the difference in the temperatures of the hot and cold junctions. If a millivoltmeter, by means of which the electromotive force generated can be measured, is introduced into the circuit, it is consequently possible to determine the temperature of the hot junction, provided that the cold junction temperature and the relation between temperature and electromotive force for the two metals used are known. The circuit can thus be used for the measurement of temperature, and a thermo-electric pyrometer consists essentially of a thermo-electric circuit in which the hot junction is exposed to the temperature to be measured, and the resulting electromotive force is measured by an indicating or recording millivoltmeter, which for convenience is usually graduated to read directly in degrees of temperature.

In a simple thermo-electric pyrometer the cold junction is placed in a constant temperature vessel, such as a vacuum flask. The two dissimilar wires, suitably insulated and protected, form the thermo-couple which is exposed to the temperature to be measured, the ends of the thermo-couple wires being connected to a millivoltmeter. The introduction of the millivoltmeter and connecting leads makes no difference to the electromotive force generated. Suitable metals must be chosen for the thermo-couple wires, the essential points being that the electromotive force developed by the junction should be sufficiently large and should increase as regularly as possible as the hot junction temperature rises, and that this electromotive force should not be altered by prolonged heating of the thermo-couple. Since the electromotive

force generated by the thermo-couple is affected by changes in the cold junction temperature, various methods have been devised for maintaining a steady cold junction temperature, such as, for example, the use of compensating leads which have the effect of transferring the cold junction from the thermo-couple head to some position less subject to temperature variations, or the immersion of the cold junction in a vacuum flask, or in an electric thermostat.

*Simple Thermo-Electric Circuit.*—In practice, a simple thermo-electric circuit is composed of the following parts:—(a) a thermo-couple, or hot junction, which receives the temperature; (b) a length of connecting leads, with or without a junction box, to make electrical connection between the thermo-couple and the millivoltmeter; (c) a millivoltmeter, which may be either an indicator or a recorder. Frequently it is desirable to have both these instruments, in which case a switch is usually required at the indicator.

*Multi-Point Thermo-Electric Circuit.*—A multi-point thermo-electric system is similarly built up of items which may be subdivided as follows:—(a) a thermo-couple or hot junction at each point where the temperature is to be measured; (b) a system of leads and junction boxes; (c) a millivoltmeter, which may be an indicator or a recorder. In combined outfits one indicator can be used in conjunction with one or more recorders. In addition a selector switch is required at the indicator, and sometimes a selector switch is required at the recorder. In addition to the above parts, and particularly for accurate work at moderate temperatures, as, for example, in outfits for determining the temperatures of stator windings, a cold junction is provided which forms a separate unit. (F. J. D.)

**THERMOMETER:** see KATA THERMOMETER.

**THEUNIS, GEORGES** (1873– ), Belgian politician, was born at Montegnée, near Liège, Feb. 28 1873. In Jan. 1916 he attended the Inter-Allied Relief Commission in London and in 1919 represented Belgium on the Reparations Commission. In 1920 he became finance minister in M. Carton de Wiart's Coalition Ministry, the aims of which Government were first to settle the reparations question, with due regard to Belgium's prior claim and secondly to maintain the entente between the Allies. M. Theunis represented Belgium at the Inter-Allied Conferences of San Remo 1920, London 1924 and Paris 1925, which resulted in the adoption of the Dawes Plan and a corresponding inter-Allied settlement. His home policy was to place Belgian finance on a sound basis and to reconstruct the devastated regions. His Cabinet resigned in April 1925, after the elections in which the Democratic parties triumphed. In Aug. 1925 M. Theunis was sent by his Government to Washington to discuss the question of the Belgian debt to U.S.A. This mission resulted in an agreement which was submitted to the Parliaments of the two countries.

**THIRD (COMMUNIST) INTERNATIONAL, THE.**—The Communist International (abb. Komintern) is the international organisation of the Communist party of all nations, founded in 1919. It is also called the Third International. In structure and programme it differs from the first and Second. Communism sympathises unreservedly with the first International, founded under the leadership of Marx and Engels, whose policy was essentially one of active revolution. As, however, its organisation lacked a definite central point and had not its roots in party associations, its practical manifestation, the Paris Commune, was bound to fail. Lenin evolved his theory of revolutionary movement from the lessons of the failure of the Commune, and arrived at the conclusion that a successful revolution might begin as a spontaneous popular upheaval, but could only achieve and retain victory in the form of an organised and systematically controlled movement. The first International lost its practical importance after the collapse of the Commune.

*Birth of the Third International.*—In 1889, when the Socialist Labour movement had recovered its force, the Second International (*q.v.*) was founded. Up to 1914 this represented the international organisation of the Socialist Labour movement as a whole. The constructive importance of the Second Inter-

national, from the point of view of the Communist parties, lay in the fact that it organised and grouped labour in trade unions, co-operatives, educational associations and political parties. The Second International already contained a Bolshevik opposition which refused to assimilate with the larger body. It was led by Lenin, who was a member of the International Bureau (B.S.I.) of the Second International in 1914. In 1914 the Second International collapsed. The Communists date the epoch of the Communist International from this moment. This epoch emerged out of a transitional period comprising the first three years of the War, during which Lenin struggled to "transform the imperialist war into a civil war." The foundations of the Third International were laid at the conferences of Zimmerwald and Kienthal in Switzerland. It only achieved real authority, however, when the leaders of the German Army conceived the idea of making the Russian February revolution more extreme. The German supreme command brought Lenin and Trotsky to Russia in the fond hope that the fire of the Russian revolution which they were kindling in Russia would stop at the frontiers of Germany.

The Third International was not formally founded till March 1919. Up to that date the Communist parties believed that they would be able to break up the Socialist parties from within and transform the Second International bodily into a Communist organisation in the tempest of the world revolution. Especially during the episodes of the Soviet Republics in Bavaria and Hungary, and even after their collapse, during the labour troubles in Britain, Germany, Italy, etc., Moscow continually believed the outbreak of world revolution imminent every hour, and expected that the Socialist parties could be simply absorbed in the Communist parties. As it grew ever plainer that this hope (which at first was shared by Lenin) was Utopian, the Communists devoted even greater energy to their own International.

*Fundamental Principles.*—The following are their basic principles:—

1. The Communist International is the organisation of the Communist parties of each nation; it is therefore revolutionary. Its chief purpose is to accelerate the development of events towards world revolution. It rejects any compromise or co-operation with bourgeois parties. Similarly it rejects parliamentarism as a normal method of political development. In certain circumstances it advocates a unity of front with Socialist parties, including the Second International. This is, however, never more than a temporary and tactical co-operation. The Communist International is honest enough to state openly that it is only ready to support the Socialist parties so far as "the hangman's rope supports the convict." The aim of the Communist International is the creation of really revolutionary proletarian parties which shall be the advance-guard of the revolution, and the combination of them in a great homogeneous international Communist party. Their headquarters are only "for the moment," as Lenin said, and probably not for long, in Moscow; later they will move to countries where the economic system and the proletariat alike are more advanced, so soon as one such country achieves a Soviet constitution.

2. The Communist International is no loose organisation like the Second International, but an association bound together by a common programme and principles, and receiving its orders from a central organ, the Bureau of the Third International. This central organ does not merely issue general rules of conduct, which may be carried out or not by the individual national parties according to their own convictions and views of the general situation; it lays down policy to the smallest details. The men at the head of Communist parties have been repeatedly changed under orders from the International, and tactics (*e.g.*, the question of co-operation with the Socialist parties, or the attitude to be adopted towards Parliament) have often been defined in detail by resolutions of the International Bureau. This central organ of the Communist International is indubitably in close personal and political touch with the Russian Govt., the Soviet of People's Commissaries.

3. The individual Communist parties are by no means all organised on the Russian system. The Communist parties of Western Europe are "open parties" which anyone may join. In some countries the Communist parties are proscribed by law. Presumably there is everywhere an inner kernel or party ring which forms the political centre. The ideas of the periphery are inspired by this inner ring. Wherever it is possible, a sort of military organisation probably also exists, exactly as in the nationalist and fascist parties.

4. In matters of internal policy the individual parties are, as already stated, strongly influenced by the Communist International,

but there are great differences between the nations. In countries where democracy is firmly based and parliamentary tradition of long standing, the tactics of the Communist parties are correspondingly modified. Communists take part in Parliament, bring forward legislative motions, etc.; at times they even co-operate with the Socialist parties. This is, however, only a temporary tactical move, the ultimate aim being always world revolution. The formation of the so-called "unified front" is a means to an end and a tactical move. The organised workmen in the trade unions are to be captured in such a way that the trade unions gradually come under the influence of the Communist parties.<sup>1</sup>

*Developments Outside the Industrial Proletariat.*—Since the aim of the Communist International is world revolution, and since the state of the Continent of Europe has grown much less disturbed since 1921, the chief aim of the Communist International proved unattainable. The revolution had taken the offensive at isolated points, but failed to develop into a world-wide movement. The International therefore put forward officially the doctrine that sudden enthusiasm alone will not bring about world revolution; this must be achieved by a strict organisation which must first be created. Such an organisation, however, presupposes a compact communist international unified front.

The Communist International began by continuing the traditional policy of the Second International. It desired to be an organisation of manual labour. But in Russia the actualities of the situation soon forced the party to admit the peasants as members (at first only the poor peasant, later the medium peasant). A Peasants' International was founded in 1923, but made slow progress. Nevertheless, it then became possible to embrace the extremist agrarian movement—a matter of the greatest importance in countries where large estates are common. The rather unexpected pronouncement was therefore made that "the peasants have become the natural allies of the workmen." Thus a link was forged with what had been the oldest revolutionary movement in Europe. To-day, indeed, with the emergence of the peasants from serfdom, their status and feelings, especially in Central Europe, have changed radically. It is most unlikely that revolutionary feelings will ever become widespread among them.

*Oriental and Colonial Propaganda.*—Far more important is the connection between the Communist International and parties and currents of thought which may be described as the heart of the movement for national and economic independence among the colonial and semi-colonial territories of Asia and Africa. Countries such as India, China and the wholly independent Japan are already represented in the Communist International by considerable parties; although these parties differ very markedly from those of Western Europe. The psychological bases for intensive Communist propaganda in Asia are, firstly, the appalling conditions in the newly developed enterprises (women's and children's labour, long hours of labour, barrack conditions for workmen); and secondly—perhaps more important—the breakdown of the social structures of these countries. Throughout Asia the family is the basis of society. Industry destroys this, and nothing comes to replace it. But man, in the Far East, cannot live except as member of a community. He cannot grasp the idea of an abstract existence, secured simply by a contract of labour. Existence is uprooted, and all his instincts revolt against an economic system which attempts to make him into an individual. This revolt finds its plainest expression in the Communist movement, the essence of which is thus the resistance of the social instincts to the destructive influences of industrial life.

Furthermore, the closing of the United States and Australia against foreign immigrants, the restrictions placed on Indian emigration to Africa, the unfortunate results which attended Chinese labour conditions in South Africa, combined with the

insistence laid by the white races on the preservation of racial distinctions, have created a real and practical feeling of unity among all coloured races and nations throughout the world—a feeling which extends throughout all Africa and Asia, and as far as the negroes of America. In the face of this racial antagonism, Soviet Russia is the only power today which stands on principle for racial equality and full equality of rights for all races on their own territory.

Thus Communist propaganda directed against the influence of European capitalists and the partisans of racial superiority in Asia has an easy task. Even Japan has been led by similar motives to a political *rapprochement* with Soviet Russia. Communist propaganda in Asia and Africa is therefore adapted to local conditions. Social and national considerations take the first place; less insistence is laid on the purely economic factor.

The resentment against capitalist exploitation, combined with the struggle against the Imperialist European Powers and against the United States, inevitably draws the leaders of those movements towards Russia, and thus towards the Communist International. This connection has been developed by special congresses to the oriental peoples (as that of Baku in 1920), and has certainly been exploited by the Russian Govt. to further Russia's traditional foreign policy in Asia. In all these countries the small tenant farmers are particularly susceptible to the allurements of the Communist programme.

*Results up to 1925.*—The Communist International forms a bond between the States organised on the Communist system and the Communist parties in the capitalist bourgeois states. In this way one may look on its work as the "formation of the front line of a world-revolution." In fact, a country which contains a strong and active Communist party finds it impossible to participate in an European counter-revolutionary movement. In terms of practical politics, this means that the States of Europe would find it hard to undertake war against Russia, in face of the opposition of their own Communists and Socialists. This is probably the greatest success of the Communist International. The Communist International is therefore both an association of national parties with a definite internal political programme, and at the same time an international political organisation of really international importance on a world-wide scale.

For an account of the propaganda methods of the Third International and the relation of the organisation to the Government of the U.S.S.R. see A. Toynbee, *Survey of International Affairs*, pp. 161 to 262 (1924). (E. L.E.)

**THOMA, HANS** (1839-1924), German painter (see 26.862), died at Karlsruhe Nov. 7 1924. He has published the following books since 1910: *Das Hans Thoma Buch* (1919); *Die suchende Seele* (1919, etc.); *Im Winter des Lebens* (1919). See C. Anton, *Hans Thoma der Maler* (1919).

**THOMAS, ALBERT** (1878- ) French politician, was born June 16 1878 at Champigny-sur-Marne, near Paris. His father was a baker who by great sacrifices enabled his son to receive a college and university education. Albert Thomas proved himself a very brilliant scholar and in 1898 he passed with distinction into the Ecole Normale Supérieure. Meanwhile he had won a scholarship entitling him to travel in Russia, which he did in the same year and published his first booklet on *Russia a Colonising Nation*. After a year of military service he re-entered the Ecole Normale and, in 1902, obtained the highest French university

<sup>1</sup> The conditions of affiliation to the Communist International prescribe that every party which desires affiliation to the C. I. must develop a systematic and persistent communist activity within the trade unions, works committees, co-operative societies, and other mass organisations of workmen. Within these organisations it is necessary to organise cells, which by persistent and continuous work must win the unions, etc., to the cause of communism. The communist cells must be completely subordinated to the party as a whole.

degree, the *agregation*; in history and geography. Afterwards he obtained another scholarship which enabled him to travel through Germany and to study the German Trade Union movement. A sequel to this was his book *Le syndicalisme allemand* (1903) in which his socialist faith was propounded for the first time.

When, in 1904, Jaurès, the great French socialist, launched *l'Humanité* he appointed Thomas sub-editor, having a high opinion of his knowledge of labour questions. Meanwhile Thomas had been elected in the same year as municipal councillor for Champigny—his first public appointment. In those days most of his activity was devoted to the Trade Union movement, for he had become one of the intellectual leaders of the "reformist" section of French syndicalism, the section opposed to the "revolutionary syndicalist" wing, which was then leading the "Confederation of Labour." He also edited a most useful and constructive magazine, *La Revue syndicaliste*. In 1908 he published in Jaurès' great *Histoire socialiste (1900-1908)* a remarkable volume on *Le second empire* which is perhaps his best book. During this time he acted as private tutor to the great-grandson of Victor Hugo, whose grandmother, Mme. Menard-Dorian, remained a great friend and supporter of the brilliant young professor and politician.

Thomas entered politics in 1909 when he stood for Parliament as candidate for his native city and was narrowly defeated by a moderate Radical. He was successful, however, in the same constituency at the general elections of May 1910 and soon made his mark in the Chamber, being elected a member of the budget committee. In the same year he supported the railway workers' general strike and strongly criticised the mobilisation of the strikers by the Prime Minister, M. Briand. In 1912 he became reporter of the bill on the miners' old age pension, having in the meanwhile been elected mayor of Champigny. He played an important part in the battle waged by Jaurès and the Socialists against the Three Years Compulsory Military Service Bill of 1913.

In May 1914 he was re-elected. He joined his regiment on the outbreak of the World War two months later. After he had seen a few weeks of War service, the "National Defence Government," newly constituted under the presidency of M. Viviani, summoned Thomas and two other Socialists, Jules Guesde and Marcel Sembat, to organise the production of munitions. In May 1915 he entered the Cabinet as Under-Secretary for Armaments and also joined the Briand ministry which followed at the end of the year. Towards the end of 1916 he became Minister of Munitions, retaining this post in the Ribot ministry which followed. In April 1917 he was sent to Russia where he remained for several months and succeeded in persuading Kerensky to undertake the ineffectual "great offensive" against the Central Powers which hastened the Bolshevik revolution.

Meanwhile in France the struggle was becoming very bitter between the majority (pro-War) and the minority (internationalist) sections of the French Socialist party, culminating in the Stockholm Conference. Leader, with Renaudel and Sembat, of the majority party, Thomas was also a strong advocate of the independence of Czechoslovakia and Poland and the creation of a "Great Serbia" and a "Great Rumania." Since this "majority wing" policy was opposed by many Socialists, particularly in the Paris district, Thomas decided not to stand again in the Paris suburbs and resigned the mayoralty of Champigny. At the elections of Nov. 16 1919 he was returned as a Socialist in the Tarn, Jaurès' former constituency. At the International Labour Conference, held in Washington at the end of the year, Thomas was elected Director of the International Labour Bureau, and as such he did much valuable work for Labour both in France and abroad. A year later he resigned from Parliament owing to the claims of his work at Geneva, but remained a member of the "right" section of the French Socialist party. For this *Encyclopædia* M. Thomas has written on Corporation and the International Labour Organisation. (J. Lo.)

**THOMAS, AUGUSTUS** (1857– ), American playwright, was born in St. Louis, Mo., Jan. 8 1857. He was educated in the public schools, for several years worked in railway freight

offices, and, after serving as special correspondent for various newspapers, became in 1886 editor and proprietor of the Kansas City (Mo.) *Mirror*. He wrote a play, *Editha's Burglar*, based on Mrs. Burnett's story of the same name, which was first produced at St. Louis in 1883 and subsequently presented with great success at the Madison Square theatre in New York in 1889. His play *Alabama* (1891), depicting the old-time South, contributed to the removal of sectional prejudice resulting from the Civil War. He was elected to the American Academy of Arts and Letters in 1912.

His numerous dramas include *In Mizzoura* (1893); *The Hoosier Doctor* (1898); *Oliver Goldsmith* (1900); *Arizona* (1900); *Soldiers of Fortune* (1902); *The Earl of Pawlucket* (1903, highly successful in England); *Mrs. Leffingwell's Boots* (1905); *Jim De Lancey* (1905); *The Winking Hour* (1907–8); *As a Man Thinks* (1911); and *The Copperhead* (1917). In 1922 he published his reminiscences, *The Print of My Remembrance*.

**THOMAS, EDWARD** (1878–1917), British author and poet, was born on March 3 1878 and educated at St. Paul's School and at Lincoln College, Oxford. His first book was a volume of nature studies, *The Woodland Life* (1897), but the first notable collection of his reflective essays was *Horae Solitariae* (1902), the predecessor of several similar, such as *Rest and Unrest* (1910) or *Clod Castle* (1922). Among a good many miscellaneous works should be noted his critical studies of *George Borrow* (1912); *Swinburne* (1912); and *Walter Pater* (1913), and a volume of stories, *Four-and-Twenty Blackbirds* (1915). But the fullest revelation of his sensitive, beauty-loving nature came when he began, under the influence of his friend Robert Frost, the American poet, to write poetry. His verse appeared in 1917 in reviews signed "Edward Eastaway," a volume of *Poems* under his own name following in that year. Serving with the Royal Garrison Artillery, he was killed in France in April 1917. His *Last Poems* appeared in 1918, and *Collected Poems* in 1920.

**THOMAS, JAMES HENRY** (1878– ), British politician, was born at Newport, Mon., on Oct. 3 1878. Entering the service of the Great Western Railway as an engine cleaner, he rose rapidly and soon became a power in Swindon (the G.W.R. headquarters) both as a trade unionist and in local government. By 1910 he had become president of the Amalgamated Society of Railway Servants and played a leading part in its reorganisation as the National Union of Railwaymen of which he was appointed general secretary after the great railway strike of 1911. Under him the N.U.R. became the leader in the policy of "industrial" or "all grades" as against "craft" trade unionism. His sagacity and influence made the N.U.R. a dominant factor both in industry and the political world.

Mr Thomas early saw that larger labour aspiration can be realised only through political action, and was an intrepid opponent both of syndicalism and of communism. He was elected member for Derby in 1910 and his services to industrial peace were recognised by his appointment to the privy council in 1917. He opposed conscription, refused to enter the Coalition Govt. and fought the 1918 election on "No more war." In the railway strike of 1919 he won important concessions for the railwaymen who, before the War, had been miserably underpaid. His book, *When Labour Rules*, published in 1920, expounded a policy of nationalisation for railways and other essential instruments of production. As Secretary for the Colonies in 1924, he showed statesmanship in his handling of the Irish and other specific issues and in his outlook on imperial problems. From the first Mr. Thomas was closely associated with the management of the British Empire Exhibition at Wembley and on this subject he has written for this *Encyclopædia*.

**THOMSEN, VILHELM LUDVIG PETER** (1842– ), Danish philologist, was born Jan. 25 1842 at Copenhagen. He took his doctor's degree in 1869 and in 1871 became a lecturer at the University of Copenhagen, where from 1887–1916 he was professor of comparative philology. In 1876 he visited England and lectured at Oxford University. Thomsen came to be known as one of the most prominent linguists of modern times and possessed an extensive and thorough knowledge of the various

classes of languages. In different linguistic fields he wrote works of very considerable importance. Of his writings dealing with Northern and East European languages may be mentioned *Den gotiske Sprogklasses Indflydelse paa den finske* (1869); *Berøringer mellem de finske og de baltiske Sprog* (1890); and *The Relations between Ancient Russia and Scandinavia and the Origin of the Russian State* (1877). In Romance philology he solved the problem of softened consonants (1876); he was the first to ascertain the palatal law in the phonic system of the Indo-European languages. In 1894 he deciphered the Orkhon inscriptions from Mongolia (*Inscriptions de l'Orkhon déchiffrées*, 1894) etc., and made in 1899 important interpretations of Etruscan and Lycian texts, and in *Turcica* (1916) he treated Ancient Turkic. Thomsen's complete articles appeared in 1919 in three volumes. He became the president of the Royal Danish Scientific Society in 1900.

**THOMSON, CHRISTOPHER BIRDWOOD**, 1ST BARON (1875– ), British soldier and politician, was born April 13 1875. Educated at Cheltenham and the Royal Military Academy, Woolwich, he served in the Mashonaland campaign and in the South African War. From 1902–5 he was instructor at the military engineering school at Chatham. In 1909 he passed on to the Staff College and in 1911 to the War Office. During the World War he served as military attaché and chief of the British military mission in Rumania (1915–6), and in Palestine (1917) and was on the Supreme War Council in 1918. Having attained the rank of brigadier-general, he resigned from the service in 1920 as a protest against Allied intervention in Russia. He joined the Labour party, and accompanied, as military expert, the commissions of enquiry dispatched by that body to Ireland and to the Ruhr; later, he visited Russia. In 1922, and again in 1923, he stood for Parliament in the Labour interest, but was unsuccessful. In 1924, he was appointed Air Minister in the first Labour Govt., with a seat in the Cabinet, and raised to the peerage. A graceful and effective speaker, Lord Thomson also possessed marked literary gifts; he wrote *Old Europe's Suicide* (1922); *Victors and Vanquished* (1924); and *Esmarana* (1926).

**THOMSON, JOHN ARTHUR** (1861– ), British naturalist, was born at East Lothian on July 8 1861, and was educated at the universities of Edinburgh, Jena and Berlin. He was, for a time, lecturer on zoology and biology at the school of medicine in Edinburgh, and in 1899 he became regius professor of natural history at Aberdeen University. Apart from his purely zoological work, chiefly on alcyonarians, Professor Thomson did much, both by his lectures and his numerous attractive books and writings, to popularise biological science, and he was indefatigable in his efforts to correlate science and religion. He made an extensive lecture tour in America in 1924.

His publications include: *Outlines of Zoology*, 7th ed. (1920); *Introduction to Science* (1911); *The Wonder of Life* (1914); *Secrets of Animal Life* (1919); *The System of Animate Nature*, Gifford Lectures (1920); *Science, Old and New* (1924); *The New Natural History* (1925); *Science and Religion* (1925) and many other books and papers on allied subjects.

**THOMSON, SIR JOSEPH JOHN** (1856– ), British physicist, was born Dec. 18 1856 near Manchester and educated at Owen's College, Manchester, and at Trinity College, Cambridge, where he was elected a fellow in 1880 and became lecturer in physics in 1883. In 1884 he was appointed Cavendish professor in the University of Cambridge and in 1919 research professor, holding in addition from 1905–18, the professorship of physics at the Royal Institution, London, and subsequently an honorary appointment. He became master of Trinity College in 1918. He developed at Cambridge a great research laboratory, which attracted numerous workers from many countries, and carried out there epoch-making investigations on the conduction of electricity through gases, the determination of the charge and mass of the electron, and analysis by means of positive rays. He became F. R. S. in 1884, and was president in 1915. He was knighted in 1908, and was the recipient of many British and foreign awards and honours, including the Royal and Hughes Medals of the Royal Society in 1894 and 1902 respectively, the Hodgkins

Medal of the Smithsonian Institute of Washington in 1902, the Nobel Prize for physics 1906, the O. M. in 1912 and the Franklin Gold Medal, 1923. During the World War he assisted various Government departments in an advisory capacity. (See GASES.)

In addition to a large number of publications in the *Proceedings of the Royal Society* and *The Philosophical Magazine*, he published *A Treatise on the Motion of Vortex Rings* (1883); *The Application of Dynamics to Physics and Chemistry* (1888); *Recent Researches in Electricity and Magnetism* (1893); *Elements of the Mathematical Theory of Electricity and Magnetism* (1895, 5th ed. 1921); *The Discharge of Electricity Through Gases* (1898); *The Conduction of Electricity Through Gases* (1903); *Rays of Positive Electricity and Their Application to Chemical Analysis* (1913 2nd ed., 1922); *The Electron in Chemistry*, Five Lectures delivered at the Franklin Institute, Philadelphia (1923); and, with Professor Poynting, a number of general text-books on physics.

**THORNDIKE, EDWARD LEE** (1874– ), American psychologist, was born at Williamsburg, Mass., Aug. 31 1874. He graduated at Wesleyan University (A.B., 1895), proceeding later to Harvard University (A.B., 1896) and Columbia University (Ph.D., 1898). He taught for a year in Western Reserve University and in 1899 became instructor in psychology at Columbia University, where in 1904 he was appointed professor. His application of statistical methods to intelligence tests constituted a notable advance in the field of psychology.

He wrote *Educational Psychology* (1903); *Mental and Social Measurements* (1904); *Animal Intelligence* (1911); *The Original Nature of Man* (1913); *The Psychology of Learning* (1914); *Psychology of Arithmetic* (1922); *Psychology of Algebra* (1923); and, in part, *The Measurement of Intelligence* (1926).

**THORNDIKE, SYBIL** (1885– ), British actress, was born at Gainsborough, Lincolnshire, and educated at the high school, Rochester, when her father, Rev. A. J. W. Thorndike, was a canon of the cathedral. From 1903–7 she toured America in Shakespearean repertory with Ben Greet. Returning to England she became a member of Miss Horniman's company at the Gaiety Theatre, Manchester, 1908–9. Her training in repertory stood her in good stead when, in 1914, she became attached to the "Old Vic" company in London. She remained there until 1918, and is said to have acted in every Shakespearean play. Her reputation as an actress was steadily growing, but it was not until 1919, when she appeared in a series of matinées at the Holborn Empire, in which she played the parts of Hecuba in *The Trojan Women* and of Candida, in Mr. Bernard Shaw's play of that name, that she attracted wide attention. Henceforward her success was assured. Among her principal parts were that of Jane Clegg in Mr. St. John Ervine's play, and Joan of Arc in Mr. Bernard Shaw's *Saint Joan*. From 1920–2 she sustained a number of leading parts in Grand Guignol at the Little Theatre, London. In 1908 Miss Thorndike married Mr. Lewis Thomas Casson, with whom she had often appeared upon the stage, and who frequently acted as her producer.

**THORNYCROFT, SIR WILLIAM HAMO** (1850–1925), British sculptor (see 26-881), died at Oxford Dec. 18 1925.

**THRACE** (see 26-885), a former Turkish province, now divided between Greece (Western Thrace) and Turkey (Eastern Thrace). Thrace was one of the three theatres of the first Balkan war of 1912, when the Bulgarians entered it and defeated the Turks in the great battle of Lule Burgas, subsequently marching up to the ramparts of Chatalja, where the armistice with the Turks was signed. With the assistance of Serbian troops the Bulgarians took Adrianople, and the Treaty of London of May 30 1913 put back the frontier of European Turkey to a line drawn from Enos on the Aegean to Midia on the Black Sea. Nearly all Thrace had thus fallen to the share of Bulgaria, but her quarrel with her allies over the spoils in Macedonia led to the second Balkan war of 1913, and the Turks took the opportunity to recapture Adrianople, to reoccupy Western Thrace and create the "independent government of Gümülcina," a mainly Moslem district.

The treaty of Constantinople of Sept. 29 1913 set back the Turkish frontier in Thrace to the mouth of the river Rezvaya on the Black Sea, considerably to the north of Midia, and, while making the right branch of the Maritsa the frontier on the Aegean, so drew the line between those points as to include Kirk Kilisse and

Adrianople within Turkish Thrace. But Gümülcina was restored to Bulgaria, with the result that 14 Moslem deputies of Western Thrace held the balance of power in Bulgaria and, under the influence of their compatriot Talaat, helped to bring Bulgaria over to the Central Empires. Meanwhile the third Treaty of Bucharest fixed the Greco-Bulgarian frontier at the mouth of the Mesta; thus the Thracian coast from the Mesta to the Maritsa gave Bulgaria her coveted outlet on the Aegean. But the frontier cut the latter river and the Mustafa-Pasha (Svilen) Adrianople-Dedeagach railway so that Bulgarian trains had to traverse Turkish territory before reaching their Bulgarian port. The Maritsa was consequently declared free to the transit of both states till they had made fresh lines on their own territories. The cession of this awkward bend in the railway to Bulgaria in 1915 was a further inducement to enter the War on the Turkish side. Thrace was not long left in peace, for the operations at the Dardanelles brought her again within the war zone. The Treaty of Neuilly of 1919 again changed her boundaries. Bulgaria was moved back from the Thracian sea coast in favour of Greece, which by Article 27 of the Treaty of Sèvres of 1920 obtained the lion's share of Thrace as far as "a point near the mouth of the Biyuk Deré" on the Black Sea, and "a point on the sea of Marmara about one kilometre southwest of Kalikratia"—in other words, up to the Chatalja lines. Thus the valuable tobacco plantations of Xanthe, and the port of Dedeagach (rechristened Alexandroupolis) became Greek.

But the Allies undertook to make the Maritsa an international river and "to ensure the economic outlet of Bulgaria to the Aegean" by Article 48 of the Treaty of Neuilly. This they effected—in theory—by "the Thracian Treaty," signed on the same day as that of Sèvres, which decreed, as a condition of the recognition of Greek sovereignty over the former Bulgarian territories in Thrace, that Bulgaria should have "freedom of transit over the territories and in the ports assigned to Greece in the present Treaty," that "in the port of Dedeagach Bulgaria will be accorded a lease in perpetuity, subject to determination by the League of Nations, of a zone," and that Dedeagach be "declared a port of international concern," free to all members of the League. In practice, Bulgaria has not availed herself of this provision, rejecting M. Veniselos' offer in 1922 of a lease of the port and preferring a corridor and actual possession. The Greek tenure of Eastern Thrace was brief. After the disaster in Asia Minor, Article 2 of the second Treaty of Lausanne of July 24 1923 restored Eastern Thrace up to the Maritsa to Turkey, leaving Western Thrace to Greece. By conventions 3 and 6, on either side of these Greco-Turkish and Bulgaro-Turkish frontiers in Thrace demilitarised zones of about 30 km. were established and existing fortifications ordered to be dismantled, and the Moslem inhabitants of Western Thrace were exempted from the obligatory exchange of populations. Thus Thrace is at present divided between Turkey, Greece and Bulgaria. A boundary question between Greece and Turkey arose later over an island at the estuary of the Maritsa.

**Economic Conditions.**—Southwestern Thrace, the most fertile portion of the country, has scarcely recovered from the damage inflicted upon it during the Balkan wars of 1912-3. The Maritsa is navigable up to Adrianople by flat-bottomed boats, but the Thracian ports are poor. Railway communications are complicated by the unscientific frontier near Adrianople, whereby the line from Western Europe to Constantinople traverses a tiny strip of Turkish territory, re-enters Greece and then recrosses into Turkey. Like all territories which have been under Turkish rule, Thrace is in a primitive condition, but the economic loss of the eastern half has been specially felt, because that would have been a field of labour for the Greek refugees. Turkish Thrace is now ethnologically overwhelmingly Turkish, while the Greeks find the remaining Moslems of the western half useful for the tobacco culture. The demilitarisation of the Gallipoli peninsula by the Lausanne Treaty should spare Thrace the spectacle of hostile armies. But the present situation (1926) may be regarded as provisional and artificial.

**THROAT:** see EAR, NOSE AND THROAT, DISEASES OF.

**THUNDER:** see ATMOSPHERIC ELECTRICITY.

**THURINGIA** (see 26.901), a territory and free state (*Einheitsstaat Thüringen*) of the German Reich. Its area is 4,541 sq. m. and the population (1926) 1,624,675.

**Political History.**—On April 30 1920 the union of the territories Saxe-Weimar-Eisenach, Saxe-Meiningen, Saxe-Altenburg, Saxe-Gotha, Reuss, Schwarzburg-Rudolstadt and Schwarzburg-

Sondershausen was recognised by a law of the German Reich on the basis of article 18, section 2, of the Constitution of the Reich. This was a natural consequence of the disappearance of the small particularist dynasties which had been removed in these States, as elsewhere, by revolutionary methods in Nov. 1918. An exception was Schwarzburg-Rudolstadt, where the Republic was established by a law enacted conjointly by the Prince and the Diet. The two principalities of Reuss had already united in one democratic state of Reuss. On the other hand, the personal union between Coburg and Gotha was dissolved, Saxe-Coburg declaring for union with Bavaria Nov. 30 1919 (ratified by the Reich April 30 1920). After the revolution all Thuringian states (except Gotha, where a Soviet régime held sway for some months) instituted elections for constituent assemblies to vote new constitutions. Meanwhile, however, the movement for union grew. All the States except Saxe-Meiningen and Saxe-Coburg concluded a preliminary "treaty of community" forming a kind of federated State with a single organ of legislation (*Volksrat*) and of administration (*Staatsrat*). Saxe-Meiningen subsequently joined this union, and on Jan. 28 1920 the Volksrat passed a law assuming the right to include within its competence the enactment of a constitution for the state of Thuringia. On May 12 1920 the provisional constitution voted by the Volksrat was promulgated and ratified with certain amendments on March 11 1921 by the newly elected Landtag.

**Constitution.**—Thuringia is a republic with parliamentary government. The diet consists of a single chamber elected on a system of proportional representation. It can be dissolved by a popular vote (*Volksentscheid*). The peculiarity of the Thuringian constitution is that the committees of the diet may call in experts to supplement their membership. The executive power is in the hands of the Ministry, which is formed on the principle of equal colleagues (*Kollegialprinzip*), and consists partly of members who hold office and partly of members who hold no office and who are designated state councillors (*Staatsräte*). The members of the ministry are appointed by the diet. The president of the ministry is chosen by the Ministry and is merely its chairman. The Thuringian constitution does not provide for any president of the state.

The legislative prerogatives of the diet are limited by the right of the people themselves to initiate legislation (*Volksbegehren*) or vote by referendum on measures already passed. After the revolution the Communists were in the majority and formed the Government, but the elections of 1924 brought a reversal; the new Government was formed by the bloc of non-socialist parties (*Ordnungsblock*). (W. v. B.)

**TIBET** (see 26.916), a country of Central Asia. Estimated area 800,000 sq. miles. Population estimated at 4,000,000. In Feb. 1910 Chinese troops entered Lhasa. The Dalai Lama and his ministers fled to India, taking their seals of office with them. The Govt. of China issued a proclamation deposing the Dalai Lama, but the Tibetans refused to recognise this. In exile at Darjeeling the Tibetan Govt. denied the Chinese claim to suzerainty over Tibet and appealed for British intervention. The British Govt., however, declined to dispute the authority of the *de facto* Govt. in Tibet. At the same time they reminded the Chinese Govt. of the necessity of respecting British treaty rights, and announced their intention of protecting Nepal, Bhutan and Sikkim, should the necessity arise for doing so.

**China and Tibet.**—Until the outbreak of the Chinese revolution in 1911 the Chinese worked steadily to consolidate their position in Tibet. But in Nov. 1911, when the news of the revolution reached Tibet, some of the Chinese garrisons mutinied, and commenced looting the Tibetan villages. Fighting followed, with the result that the Tibetans overpowered the Chinese troops in central Tibet and deported them across the Indian frontier. In June 1912, the Dalai Lama returned to his country. Throughout eastern Tibet the Chinese were able to maintain most of their ground. In July 1912, a Chinese force was again dispatched to Tibet but failed to make much headway, and was withdrawn after representations had been made by Great Britain at Peking to the effect that such action contravened the convention of 1906.

At the end of 1912 Russia concluded a convention with Mongolia. This was signed at Urga, the Mongolian capital. Russia agreed to assist Mongolia in preserving her autonomy against China, and received in return extensive economical and political

privileges in that country. This convention was followed by what purported to be a treaty between Mongolia and Tibet, but the validity of this latter document is questionable. Towards the end of 1913 a Russo-Chinese treaty confirmed the Russo-Mongol convention.

*A Futile Conference.*—During 1913 the Chinese resumed hostilities and endeavoured also to negotiate with the Tibetan Government. The latter declined to meet any representatives from China unless a British representative were also present at the conference. Accordingly, in Oct. 1913, plenipotentiaries from the three countries assembled at Simla to discuss and to define the political status of Tibet. China was represented by Mr. Ivan Chen, Tibet by Lönchen (a title denoting chief minister) Shatra and Great Britain by Lt. Col. Sir A. H. McMahon. After six months' discussion the three plenipotentiaries initiated a convention by which:—

- (a) Chinese suzerainty over Tibet was recognised.
- (b) Tibet was divided into "Inner Tibet," the part nearer China, and "Outer Tibet," the part nearer India. The latter was to be autonomous, the former under a considerable measure of Chinese control.
- (c) The Chinese Amban was to be re-established at Lhasa with a suitable military escort.
- (d) A fresh trade treaty was negotiated between India and Outer Tibet.
- (e) The frontier between Tibet and northeastern India was settled.

The Chinese Govt. refused to ratify the convention, explaining that its sole objection was to the frontier between China and Tibet as established by the convention.

After the break-up of the conference the Chinese and Tibetan Govts. agreed to suspend hostilities against each other pending a renewal of the negotiations. In 1917, however, fighting was resumed, the Chinese general on the frontier being apparently responsible. In the campaign that followed the Tibetans were victorious. Driving the Chinese out of the districts of Mangkam, Traya and Chamdo, they recaptured their territory as far east as the Yangtze Kiang. In July 1918 a truce was arranged by the British vice-consul, the Tibetans retaining the lands which they had reconquered but advancing no further.

*The War and After.*—During the World War the Govt. of Tibet offered 1,000 Tibetan soldiers to fight on the British side and further ordered that special services for the success of the British arms should be held from time to time in the leading monasteries throughout Tibet. An event of some significance occurred about this time in the dispatch of four Tibetan boys of the upper middle class to England, where they received, so far as the time at their disposal allowed, an English education. In 1919 the Chinese Govt. at Peking proposed a renewal of the negotiations abandoned in 1914, but subsequently withdrew their proposals, as they met with strong opposition from their own countrymen. Early in 1920 a Chinese mission visited Lhasa and remained there four or five months, but left without coming to any settlement with the Govt. of Tibet.

Towards the close of 1920 Mr. (afterwards Sir) Charles Bell, the British representative in Tibet, was dispatched to Lhasa at the request of the Tibetan Govt., the first mission from any country outside China to be invited to the Tibetan capital. As a result of the mission, which remained a year in Lhasa, it was decided to afford the Tibetan Govt. such reasonable assistance in the settlement and development of their country as might be expected from a friendly neighbour more advanced than themselves. The desire of Tibet for closer co-operation with India was further shown by her request for the linking up of Lhasa with the Indian telegraph system. This was effected during the summer of 1922. The Tibetan Govt. are thus enabled to communicate with India and receive an answer the same day instead of waiting seven days for the reply.

In 1926 the position of the Sino-Tibetan dispute was that Tibet desired a settlement. But there is a strong body of public opinion in China opposed to recognition of the standing which Tibet claims, and, even if a settlement were reached with the Chinese Govt., the latter is not strong enough to impose it on Kansu,

Szechwan and Yunnan, the three provinces that are chiefly concerned with Tibet. Since 1912 the Tibetan Govt. has maintained complete independence of China. Her military strength appears to be slowly increasing, but is hampered by shortage of funds, for the country is poor, and a large share of the revenue is alienated to the priests and the nobility.

*Trade, etc.*—The trade between Tibet and India is expanding slowly. Minerals have not yet been discovered on such a scale as to warrant their being exploited commercially. During recent years a mint has been opened at Lhasa. Gold, silver and copper coins are minted. A limited number of currency notes have been put into circulation, the value of these ranging up to 50 tankas (=about 16 shillings). One of the four Tibetan lads who came to England for education is understood to be starting a small hydroelectric scheme in Lhasa.

**TIDAL POWER.**—The idea of utilising the rise and fall of the tides for power purposes has long attracted the attention of inventors, and many ingenious schemes have been suggested. So far, however, the only practicable method is based on the use of one or more tidal basins, separated from the sea by dams or barrages, and of hydraulic turbines through which the water is passed on its way between basin and sea or between one basin and another.

Any simple tidal power scheme suffers from the disadvantages that the working head is both low and variable, not only from day to day but also over any one tide; and that the turbines cease to operate for a more or less extended period on each tide. Moreover since this idle period depends on the time of high and low tide it gradually works around the clock, and will, at regular intervals, be included in the normal working day. While schemes of operation are feasible in which the idle period may be eliminated this involves a large reduction of output per square mile of tidal basin area. Even in such schemes, unless the working head and the output be limited to that available at the lowest neap tides there is still a large variation of output between springs and neaps. On the other hand, with such a limitation the power developed is only a small fraction of the total energy available, and the cost of the necessary engineering works per horse-power-year will be prohibitive except under exceptionally favourable circumstances.

In order to obtain a continuous output of energy, or an output suitable for any ordinary industrial load, some storage system is necessary, unless the scheme is connected with some steam or inland water power station capable of equalising the supply at the idle periods and during the neap tides.

*Storage Systems.*—Various storage systems have been suggested, such as electrical accumulators, electrically heated steam boilers, and those using compressed air. At present the most promising consists of an elevated storage reservoir supplied from pumps driven from the turbines at times of excess supply, and feeding a battery of secondary turbines. The method is, however, only possible where there is a suitable elevated site within reasonable distance of the tidal basin.

*Types of Schemes.*—Briefly outlined the more promising of the schemes of tidal power development are as follows:—

- (a) A single tidal basin is used, divided from the sea by a dam in which are placed the turbines. The basin is filled through sluices during the rising tide. At high tide these are closed. When the tide has fallen through about one-half its range, the turbine gates are opened and the turbines operate on a more or less constant head until low tide or slightly after. If  $A$  be the surface area of the basin in square feet; if  $H$  ft. be the tidal range; if a constant working head of  $h$  ft. be adopted; and if the turbines operate until low tide, the volume of water used during the falling tide will be  $A(H-h)$  cu. ft., and the energy available in the water will be

$$64 A(H-h) \text{ ft. lb. per tide.}$$

This expression is a maximum when  $h = H/2$ , that is when the working head is one-half the tidal range, and then equals  $16 \cdot A H^2$  ft. pound.

If  $A$  is in square miles, and if the efficiency of the turbines is 75% the output in horsepower-hours per tide is given by

$$\frac{0.75 \times 64 (5280)^2 A H^2}{4 \times 33000 \times 60} = 169 A H^2$$

The cycle of operations is shown in fig. 1 where  $AB$  denotes the working period and  $CD$  the period of replenishment of the basin. The sine curve represents the level of the sea outside the basin. Owing to the great variation in the rate of efflux of the water in this constant-head method of operation, the power output varies very largely during the falling tide. This variation may be reduced con-

Fig. 4.

#### SCHEMES OF TIDAL POWER DEVELOPMENT

FIG. 1.—Single tidal basin, divided from sea by a dam in which are placed the turbines. FIG. 2.—Single tidal basin, with turbines operating on rising and falling tides. FIG. 3.—Two tidal basins, with turbines in dividing wall. FIG. 4.—Two tidal basins, with turbines installed in walls dividing the sea from each basin.

siderably by allowing the turbines to operate on a more or less constant fall of level in the basin as shown by the straight full line  $AB$ . By this method of operation the necessary turbine capacity for a given output may be greatly reduced. By extending the working period beyond low tide, as indicated by the dotted line  $AE$ , a greater amount of energy may be developed per tide and the idle period is diminished, but at the expense of an appreciably greater variation in head. The most efficient combination of working period and of working heads can only be determined by detailed examination of the particular site, and with a knowledge of the exact form of the tidal curve.

(b) A single tidal basin is used, with the turbines operating on both rising and falling tides. The cycle of operations is indicated in fig. 2. The working period per complete tide now extends from  $A$  to  $B$  and from  $C$  to  $D$ . Slightly before low water, at  $B$ , the basin is

emptied through sluice gates, and at  $D$ , a little before high water, the basin is filled through the sluice gates. With a working head equal to one-half the tidal range, the period of operation is approximately 60% greater than in system (a) with operation down to low tide, and the work done per complete tide is some 60% greater.

(c) Two basins of approximately equal areas are used, with turbines in the dividing wall. Each basin communicates with the sea through suitable sluice gates. In one of these basins, called the upper, the water level is never allowed to fall below one-third of the tidal range, while in the lower basin the level is not allowed to rise above one-third of the tidal range. The working head then varies from  $0.53 H$  to  $0.80 H$ , with a mean of approximately  $0.66 H$ , and operation is continuous as indicated in fig. 3, which shows the cycle of operations. Between  $A$  and  $B$ , the upper basin is filled from the sea through appropriate sluice gates, and the lower basin discharges into the sea from  $C$  to  $D$ . For a given total basin area and a given tidal range, the output is only about one-half that obtained in system (a) and one-third that obtained in system (b), so that except where the physical configuration of the site is particularly favourable the cost per horsepower is likely to prove very high.

(d) Two tidal basins of approximately equal areas are used. Turbines are installed in the walls dividing the sea from each basin. Fig. 4 shows the cycle of operations. From  $A$  to  $B$  the upper basin discharges through its turbines into the sea. From  $B$  to  $E$  the sea enters the lower basin through its turbines. The upper basin is filled from the sea through its sluice gates between  $C$  and  $D$ , and the lower basin is emptied through its sluice gates from  $F$  to  $G$ . The head varies from  $0.25 H$  to  $0.62 H$ , and the output is some 25% greater than in system (c), but the number of turbines required is much greater.

It is possible to arrange in each of these systems that the head shall be maintained constant during any one working period, but since this means that the working head is then limited to the minimum obtaining during that period, a loss of energy is involved, with a great additional cost of construction and complication in manipulation and with little compensating advantage.

For any scheme of development involving the use of a tidal estuary of such type as is found in the Severn or Dee, the cost of any of the multiple basin systems would appear to put them definitely out of court.

A scheme involving operation only on a falling tide has the disadvantage that the output is only about 60% of the output theoretically possible with double-way operation. On the other hand the output per unit of turbine capacity is sensibly the same, while it enables a much more efficient type of turbine setting to be used, and enables the number of sluice gates to be halved. It has the further advantage, where applied to a navigable river, that the depth of water in the basin never falls below mean tide level or thereabouts, so that navigation above the barrage is improved. The scheme is essentially more simple than any one involving double-way operation.

**The Severn Scheme.**—Up to the present (1926) no tidal scheme of any magnitude has been constructed. The possibilities of such an installation on the estuary of the Severn are, however, now under consideration by a committee appointed by the British Government. This would consist of a single tidal basin of about 25 sq. m. in area formed by a barrage probably in the neighbourhood of Sudbury, along with a storage reservoir some 500 ft. above sea level and about five miles away above the Wye Valley. Single-way operation of the turbines is proposed. It is estimated that the scheme would be capable of developing some 500,000 H.P. over a 10 hour working day throughout the year.

**Fundy Bay Scheme.**—Designs have also been prepared for a two-basin scheme for utilising the tides at Passamaquoddy Bay, an inlet of the Bay of Fundy in Nova Scotia, from which it is estimated that between 500,000 and 700,000 horsepower can be generated.

**Aber-Vrach Scheme.**—A scheme to which the French Government is giving financial assistance is projected at Aber-Vrach on the coast of Brittany, and appears likely to be undertaken almost immediately. For the tidal operated station a barrage 490 ft. long is to be constructed in the estuary. Four turbines connected to synchronous generators are to be installed, each capable of developing 1,200 H.P., under the maximum head available at spring tides. The turbines are to operate both on the ebb and flow tides. This station will work in conjunction with an auxiliary water-power station some 4 m. away on the river Diouris. The

river is to be dammed at this point, forming a fresh water reservoir from which turbines having a maximum capacity of 2,700 H.P. are to be supplied. Electrically driven centrifugal pumps of a capacity of 3,200 H.P. will also be installed.

During the idle periods of the tidal station, and during neap tides, the river plant will be used. As the tidal turbines come into operation the river plant will be shut down and finally when the tidal power becomes in excess of the demand the alternators at the river plant will be run as motors to operate the pumps, which lift water from the lower to the upper side of the river dam. It is anticipated that the combined plant will make it possible to maintain a continuous output having a maximum of 3,200 H.P. and a minimum of 1,600 horsepower.

**BIBLIOGRAPHY.**—A. M. A. Struben, *Tidal Power* (1921); A. H. Gibson, *Hydro-Electric Engineering*, vol. 2 (1922); N. Davey, *Studies in Tidal Power* (1923). (A. H. GL.)

**TIDES** (see 26.938).—During the present century there has been a marked increase in the interest taken in tides.

**Observation.**—The observation of coastal tides by means of automatic gauges has been continued in most countries, but comparatively little has yet been done in the measurement of off-shore elevations. A number of attempts have been made to construct a self-registering gauge which, when placed on the bottom of the sea, will give a continuous pressure-time record. From such a record it is of course easy to pass to an elevation-time relation. The gauge which appears to have met with most success is that of L. Favé, of the French Hydrographic Department. The continuous measurement of currents has been continued, though not to the extent which the importance of the work warrants. Owing chiefly to the trouble of keeping a meter fixed relatively to the sea-bottom the accurate measurement of currents is attended with considerable difficulty. For the valuable series of observations taken in the North Sea much credit is due to the International Council for the Exploration of the Sea, which has its bureau at Copenhagen.

**Harmonic Analysis.**—In 1920 J. Proudman wrote for the British Association a report on work in the British Empire of Harmonic Analysis, and pointed out that much remained to be done on the subject. The harmonic constants did not represent completely the records analysed; for certain British stations the discrepancy reached a semidiurnal range of one foot and a quarter diurnal range of one foot. Also, the numbers obtained for the same constant from different records showed considerable variation. Since then much attention has been given to the subject, notably by A. T. Doodson, of the Liverpool Tidal Institute, which was established in 1919. He has made a new development of the generating potential, working to a much higher order of approximation than G. H. Darwin, and making it truly harmonic instead of grouping together a number of terms to form a slowly varying constituent. He found that there is a very large number of other terms which, while certainly smaller than those of Darwin, are not very much smaller and in their aggregate may be important. In other words, the convergence of the series of constituents is not so rapid as had been assumed. A corresponding state of affairs exists with regard to *over tides* and *compound tides*. For certain British stations Doodson has found it possible to obtain a practically complete representation of the quarter diurnal tides, but it involves many more harmonic constituents than had previously been sought for by the customary methods. He has also been able to account for part of the variation in the numbers obtained for harmonic constants. P. Schureman, of the United States Coast and Geodetic Survey, has published a list of harmonic constants for 840 stations. *Tide Tables* can still not be regarded as completely satisfactory even for such practical purposes as docking large vessels and navigating over shoals. The main deficiency appears to be one of analysis of records.

**Geographical Distribution.**—Observation has now provided us with a good knowledge of the principal tidal constituents along all the coasts of the world, but very little is yet known for certain as to their distribution over the oceans. General theory indicates that somewhere in the oceans there will be "amphidromic points," i.e., points at which there is no rise and fall of the

water and from which the cotidal lines radiate. A knowledge of the position of these points would summarise a large amount of information, and consequently much attention is paid to them. In 1920 R. Sterneck prepared world-charts for the chief semi-diurnal and diurnal constituents, based on all available data, but they must be regarded as largely hypothetical. The charts differ in many important respects from those of R. A. Harris, though there is much similarity for the North Atlantic. Where tidal currents have been well observed, fundamental mechanical principles lead to much information regarding the tidal elevations. An example of this is afforded by the North Sea, the principal constituent of the tides of which may now be regarded as well known over the whole area. The investigation has been carried out since 1920, and so far is almost entirely restricted to the North Sea.

**Dynamical Theory.**—The tides of any body of water are dynamically determinate when either the elevations or the normal currents are known along the sections which are taken as dividing the body from other waters. In explaining the tides of any particular sea or ocean, it is therefore necessary to assume either from observation or from other theory the tidal conditions in the water immediately neighbouring. The detailed explanation, on dynamical principles, of observed tides has so far been restricted to the elongated basins of narrow seas, channels and gulfs. The work is due chiefly to A. Defant and R. Sterneck and has all been carried out since 1910. It rests on the principle that for such basins the tidal currents are non-rotating and parallel to the general direction of the basin. In these circumstances the motion of the water may be regarded as a longitudinal oscillation with an oscillating transverse surface-gradient sustained by the currents in virtue of the earth's rotation. The differential equations are constructed after the manner introduced by G. Chrystal for the seiches of elongated lakes, and are then solved by numerical step-by-step methods. Applications have been made to the tides of the Red Sea, the Persian Gulf, the English Channel, the Irish Sea and the Adriatic Sea. When the transverse currents cannot be neglected the theory presents much greater difficulty. Even for the North Sea a complete detailed dynamical explanation has not yet been given, though it is possible to give a qualitative one. In 1911 R. Witting proposed an explanation of the Baltic tides, and later R. Sterneck proposed explanations of those of the Mediterranean and Black Seas. Their methods are largely those which apply to narrow seas, except that they are used transversely as well as longitudinally. No generally accepted detailed explanation of the tides of the great oceans has yet been given, though A. Defant has recently made an attempt for the Atlantic and Arctic basins.

As regards the tidal dynamics of geometrically simple bodies of water it is convenient to consider separately closed and open basins. Of the former the only cases which had yielded to mathematical treatment up to 1914 were those of a flat circular sea whose depth is a function only of the distance from the centre, and an ocean covering the whole globe, with the depth a function only of the latitude. The details for polar and zonal basins of uniform depth were worked out by G. R. Goldsbrough in 1914, while the solution for a flat rectangular sea of uniform depth was given by G. I. Taylor in 1920. For open basins the most important contribution is G. I. Taylor's solution (1920) for the tides in a rectangular gulf of uniform depth. When modified to allow for friction the results provide a first approximation to an explanation of the tides of the North Sea. At a later date J. Proudman investigated the tides of a channel whose section is uniform along the length but of varying depth from side to side, obtaining results which indicate the degree of error in the assumption of no transverse current in narrow seas. Other parts of the dynamical theory which have undergone development relate to the effects of capes, bays and islands on local tides, to slowly rotating seas and oceans and to limiting forms of long period tides. In the last connection it should be mentioned that there is an erroneous statement in 26.958; viz., that continental barriers have the same effect as that attributed by Laplace to friction. That this is not necessarily the case has been emphasised by E. Fichot.

Two attempts have been made to bring some of the latest methods of pure mathematics to bear on the general problem. In 1910 H. Poincaré transformed the dynamical equations from the differential to the integral form. The theory of integral equations has grown up almost entirely since 1900; its results are perfectly general, and are stated explicitly in terms of direct operations. But in the case of tidal problems the arithmetical labour necessary to carry out these operations is so prodigious as to prove quite prohibitive even for the reproduction of known solutions. Nevertheless, the theory is valuable for the establishment of existences, and in 1923 was further developed by G. Bertrand. In 1917 J. Proudman specified the tidal state of an ocean by means of an infinite number of co-ordinates of the Lagrangian type, and then transformed the differential equations into an infinite set of linear algebraic equations.

**Friction.**—If tidal motion were everywhere non-turbulent the amount of friction in the tides would be quite insufficient to account for the outstanding discrepancy between theory and observation in the motion of the moon. But tidal currents in shallow seas are undoubtedly turbulent, and though this has long been recognised it was left for G. I. Taylor in 1920 to make a numerical estimate of the associated dissipation of energy.

H. Jeffreys concludes that the total amount of friction is just sufficient to account for the discrepancy mentioned. He takes the chief contributing areas to be Behring Sea, the Yellow Sea, Malacca Strait and the N.W. Passage. Assuming the magnitude of the ocean tides to be of the order given by the equilibrium theory, Jeffreys calculates that the total energy at any time present in the oceans is only equal to that dissipated by friction in about two days.

**TIENTSIN**, China (*see* 26.963), with a population estimated variously at from one to two millions (including 683 British in 1925), is now the leading port of northern China and the principal outlet for the produce of four provinces. The trade of the port has grown rapidly, particularly with the United States and increased 100% between 1917 and 1923. Commerce in eggs, carpets and marmot skins has developed. Till 1920 the harbour was closed each winter by ice, but in that year three powerful ice-breakers were installed. Tientsin handles a third as much trade as Shanghai.

In 1925 the authorities of the seven concessions were reclaiming land within their limits to cope with the need for houses and offices. The municipal services are very efficient, and the streets of the concessions are in good condition. A large electric light company started work in 1912. Tientsin is an important railway centre, with a line to Pukow and a station on the Pekin-Mukden line. A distributing, not an industrial, centre, it has a number of cotton mills, and distilling and salt-evaporation are large local industries. The concessions have been rapidly developed. The former German and Austrian concessions were taken over by the Chinese authorities in 1917 and the two British concessions were amalgamated in 1918. The disastrous floods of 1917, when the Grand Canal burst its banks, carried away the main railway line to Pukow and flooded the concessions, led to the formation of a commission to consider the problem of the Chih-li river. An outer dike at Tientsin, a cutting which

shortens the course of the Hai-ho and does away with some difficult bends, and an outlet for the Machang channel have been made. Other plans were considered in 1924, when further severe floods occurred. In 1925 the banks of the Grand Canal were strengthened.

**TILAK, BAL GANGADHAR** (1856-1920), Indian nationalist leader, a Chitpavan Brahmin, was born at Ratnagiri July 23 1856. At an early age he took the lead in providing education in Poona under Indian direction. In 1890 he was proprietor and editor of two weekly papers, *Mahratta*, printed in English, and *Kesari (Lion)*, printed in Marhatti, which organs he used for anti-Government propaganda. His violent condemnation in 1897 of the plague prevention regulations resulted in his being convicted for sedition and sentenced to 18 months' imprisonment. For the same offence he was sentenced in 1908 to six years' transportation, subsequently commuted to simple imprisonment in Mandalay. After his release he took an active part in the home-rule campaign, and secured for his party the control of the National Congress. He died in Bombay on Aug. 1 1920. His paper on the *The Orion, or Researches into the Antiquities of the Vedas*, read at the International Congress of Orientalists in London 1892 (published at Poona 1893), expounded a theory of extremely remote Aryan origins, which has not been accepted by other scholars. His formative part in the cult of Indian unrest is shown in the report of the Rowlatt sedition committee (1918). His speeches are collected in *Lokamanaya B. G. Tilak* (2nd ed. Madras, 1920).

**TIMBER:** *see* FORESTRY; NATURAL RESOURCES, CONSERVATION OF.

**TIME:** *see* SPACE-TIME.

**TIME SALES.**—The second of the factors which played a great part in expanding the market for motor cars was the practice of selling under the time-payment plan. For a long time the automobile business was conducted on a cash basis. The purchaser made a deposit of from 20 to 30% at the time of placing his order, and paid the balance upon delivery. No difficulty was experienced in enforcing these terms, because the demand for cars ran ahead of the capacity of the factories to produce. Gradually, however, production caught up with the demand, and it then became necessary to create a market among those classes of the population which generally are not well supplied with ready money. Under the time payment plan, introduced to this end, the purchaser makes an initial payment of perhaps 33½% when receiving his car, and the remainder is paid in monthly or weekly installments. *See* INSTALLMENT SELLING.

**TIN** (*see* 26.995).—Although deposits of tin are widely distributed, the two areas of chief importance are the Asiatic deposits, comprising Malaya, Siam and China, and those of Bolivia. These two areas provide about 85% of the world's total output. Until 1916 the British Empire production exceeded that of foreign countries; but since that date, owing to the enlarged output from Bolivia and the Dutch East Indies, the production of foreign countries has been the larger. In 1925 the world's most important producer of tin was still the Federated Malay States where the alluvial deposits of the Kinta valley form the richest tinfield. The methods of working are ground sluicing and hydraulic mining; open cast-workings; underground workings and dredging. In Burma the most important occurrences of tinstone are in the Bawlake State of Karenni, at the Mawchi Mines, in the Amherst district (a) at Belugumy, (b) east and west of the Seludang range; and in the Thaton, Tovoy and Mergui Districts.

The Burmese mineralised belt continues southwards through the F.M.S. to the Islands of Singkef, Banka and Billiton in the Dutch East Indies, thus forming the world's richest tin-producing area. In 1924 it supplied over 60% of the world's total output; and the Dutch East Indies alone contributed no less than 23.2% of the world's production. It was, however, stated in 1925 that within 12 years the bulk of the rich secondary deposits of Dutch East Indies, of Malaya, of Siam and of Lower Burma will have been exhausted. Other Asiatic occurrences of tin are those of French Indo-China in the Province of Tongking; in China, in the provinces of Yunnan, Kwangsi, Hanan, Kwangtung and Fukien;

and in Japan in (a) the Akenob district, Tajima province, (b) the Taniyama mine, Satsuma province, (c) the Kiura mine, Bungo province, (d) mines near Takayama and Hirukawa, Mine province.

In North and Central America cassiterite is known to occur in very small quantities, also in Canada, United States, Mexico and British Honduras. The most important producer in South America is Bolivia, whose tinfields supplied 21.4% of the world's total output in 1924. The chief mines occur in La Paz, Cochabamba, Oruro and Potosi. The most important point about the Bolivian deposits is that they are primary, and lode-mining is much more likely to yield larger outputs over a longer period of future years than is the case with the Asiatic deposits. Tin is widely distributed in Australasia—all the States of the Commonwealth of Australia and also New Zealand produce the mineral—but in 1923 the whole area yielded only 2½% of the world's total production.

In the continent of Africa the most important tin producer is Nigeria (Bauchi plateau), followed by the Union of South Africa and Swaziland. Other contributing countries are the Gold Coast, Nyassaland, Belgian Congo, Portuguese East Africa, South West Africa and Rhodesia. In 1924 the continent of Africa produced 5.47% of the world's production of tin for that year, of which 4.47% was contributed by Nigeria.

In Europe the chief producing countries are Great Britain, Czechoslovakia, Germany, Portugal and Spain. With regard to the mines in Cornwall and Devon, during the 50 years ending 1800 the output varied between 2,000 and 3,500 tons a year. The maximum output during the War was 6,537 in 1914. By 1922, when so few mines were working, the production was only 370 tons. By 1924, owing to the greatly improved conditions, the figure had risen to 1,725. In 1925 about 95% of the production occurred in the Camborne-Redruth area.

The following table gives the world's production, in long tons, of tin ore for 1913, 1918 and 1923.

|                                      | 1913    | 1918    | 1923    |
|--------------------------------------|---------|---------|---------|
| United Kingdom . . . . .             | 5,288   | 3,954   | 1,021   |
| Nigeria . . . . .                    | 3,872   | 5,904   | 5,860   |

**TIRES** (see 26.1006).—Structurally tires are divided into two main classes: solid rubber and pneumatic. The cushioning properties of solid (American) or band (British) tires come from the elasticity of the rubber and the depth of the tread. There is a sub-class of solid tires, designated by the name of cushion tires. In pneumatic tires compressed air serves both as the cushioning and load-supporting medium. The rubberised fabric structure

of the casing in this case serves as a flexible, yielding container for the compressed air.

**History.**—In 1910 the motor-vehicle industry used the "clinch" or "beaded edge" pneumatic tire constructed with square woven fabric. These tires in 1910 averaged only 3,000 to 4,000 m. of service. The clincher design of the rim and bead combination (fig. 1) as a method of attachment of tire to the rim had its limitations, particularly in the larger sizes, so that progress in improving the service of tires of this type was discouraging. The principle of the bead of the Dunlop-Welch wired-on bicycle tire was then developed and introduced under the name of the "straight-side" bead. This idea first became practical for motor-vehicle use in 1907, when an American manufacturer (the Goodyear Tire and Rubber Co.) offered to the American public its "detachable" straight-side rim and tire (fig. 2). Its progress was slow because of competitive hindrances, but by 1910 the merits of the detachable rim obliged the clincher tire manufacturers to furnish some sort of a detachable tire. The result was the "quick-detachable" (Q.D. clincher), a tire fitting a detachable clincher rim and having its beads shaped like the regular soft bead clincher, but with an inextensible wire bead core like the straight-side tire. During this period of development, the Q.D. clincher served as a transition type.

The merits of the straight-side construction, however, gradually made it more popular than the Q.D. clincher, with the result that the last Q.D. clincher rims were made in 1916. In the meantime the European demand continued to be for the clincher type exclusively, while they were discontinued in American production except for the use of clinchers in the Ford sizes.

Progress in details of design, materials and methods of manufacture was very gradual, the general idea being always to build a "balanced" tire, that is, one in which all parts were equally durable. The straight-side tires of square woven fabric of 1920 averaged 5,000 to 6,000 m. of service and required air pressure ranging from 55 to 75 pounds. About 1912 electric automobiles in America created a demand for "power saver" tires, to which

FIG. 2.—Perspective of straight-side tire on rim.

the tire makers responded by offering special casings of "cord" fabric structure for which exceptional resiliency and lack of internal friction were claimed. This tire was not at all durable at first, but as it was gradually perfected, the leaders of the industry became convinced that it (what is now called the "high-pressure" cord tire) was to be the quality tire of the future (fig. 3).

**The Cord Tires.**—Ply separation and fabric breaks in cord tires are effectively prevented because the cords, being completely insulated from each other, provide a flexibility of the "carcass" without chafing, that greatly reduces injury from under-inflation and overloading. The two-ply "cable" cord

construction was the initial form, and the "multi-ply" construction (The Goodyear Co.'s contribution) soon followed. In 1920 the merits of the multi-ply construction had prevailed to such an extent that the cable cord was no longer made. After the World War European tire manufacturers began to duplicate

FIG. 3.—Cross section of high-pressure straight-side tire.

FIG. 4.—Cross section of balloon tire.

American multi-ply cord construction in their millimetre beaded-edge sizes. The cord tires of 1920 averaged 7,000 to 8,000 m. of service and required air pressure of 45 to 65 pounds.

**The Balloon Tire.**—The next major development in automobile tires came with the introduction of the balloon tire. This type was first developed, perfected and put on the market by the Firestone Tire and Rubber Co., the fundamentals underlying this development being, first, to make it possible to owners to use air pressure ranging from 25 to 35 lb.; second, to use a much larger cross section of tire in combination with a smaller diameter of rim so that the overall height of the tire would remain the same; and third, to use only four plies of cord in the carcass construction in order to give the extreme flexibility which would be necessary for use with low pressures, and at the same time to secure the durability which the public demanded (fig. 4). By way of example in showing the relationship between high-pressure cord tires and the balloon type, the following table is included to give typical examples:

| High-Pressure Tires |                   |           |                 | Balloon Tires |           |                 |
|---------------------|-------------------|-----------|-----------------|---------------|-----------|-----------------|
| Sedan Models        | Size              | No. Plies | Proper Pressure | Size          | No. Plies | Proper Pressure |
| Ford                | 30x3½<br>Fab. Cl. | 4         | 55 lb.          | 4'40-21       | 4         | 30 lb.          |
| Buick               | 31x4              | 5         | 60 lb.          | 5'25-21       | 4         | 34 lb.          |
| Dodge               | 32x4              | 6         | 60 lb.          | 5'77-20       | 4         | 35 lb.          |
| Willys-Knight       | 32x4½             | 6         | 60 lb.          | 6'20-20       | 4         | 30 lb.          |
| Paige               | 33x4½             | 6         | 65 lb.          | 6'75-21       | 4         | 34 lb.          |
| Packard             | 33x5              | 8         | 65 lb.          | 7'30-20       | 4         | 30 lb.          |

The improved riding comfort secured from the use of balloon tires brought them into general use very rapidly; the first being sold for change-overs and put on cars by manufacturers as original equipment in the early autumn of 1923. By the autumn of 1924 they were used as original equipment on nearly all cars except Fords, and the Ford Co. adopted them to replace the clincher fabric tires early in 1925. In 1925 the high-pressure cord and balloon tires reached such perfection that the cord tires averaged from 12,000 to 14,000 m. and the balloon tires between 16,000 and 18,000 miles.

To summarise the progress of pneumatic tire development over the period of 1910 to 1925 from a dollar-and-cents standpoint, we find that the tire cost per mile on a medium size car diminished as follows:

| Period         | 1910-2   | 1913-5   | 1916-8   | 1919-21  | 1922-5   |
|----------------|----------|----------|----------|----------|----------|
| Tire Mile Cost | \$0.0112 | \$0.0055 | \$0.0041 | \$0.0030 | \$0.0016 |

The balloon tire development in America was entirely on straight-side rims with the standard flat base design. The Dunlop Rubber Co. in England simultaneously developed balloon

tires similar to those used in America, with rims worked out in the straight-side type with the drop centre design, as on the old Dunlop-Welch wired-on bicycle tire.

**Tires for Motor Trucks.**—In 1915 the Goodyear Co. started actively to develop large, heavy construction pneumatic tires for use on motor-trucks. Beginning with 1916 all activities in this line were confined to the cord construction which gradually developed in 6, 7, 8, 9 and 10 in. sections, ranging from 10 to 16 plies, and employing from 90 to 130 lb. of air. To carry the load, in some cases, it was necessary to use the tires in dual or twin application on the rear wheels. The use of these tires was very limited, however, until the period of motor-bus expansion which began in 1921, so that truck or bus tires, as they were called, came into large production by 1925 in both single and dual application. The average mileage of these tires on buses varied over a wide range due to the different classes of service; in some localities as low as 12,000 m. while in other places as high as 25,000 miles. In 1925 the balloon-tire principle was introduced into bus application by the Firestone Co., by bringing out what was known as "balloon bus tires," designed to run with from 45 to 50 lb. of air.

**Solid Tires.**—The typical solid tire of 1910 was the British "pressed-on" band tire (fig. 5), then in use in Europe and soon to be duplicated in America. These tires were fitted to the wheels by simply forcing or pressing on with a special press, but in the absence of conveniently located tire presses, some American manufacturers adapted the metal-base idea to a "bolted-on" design (called "Demountable"), having bevels on the inside edges of the steel band so arranged that hoop-shaped "wedges" could be fitted to mount the tire, the whole assembly being bolted in place with "side flanges." Early metal base tires in America failed prematurely from fracture of the exposed hard rubber at the edge of the base band due to rough streets. To remedy this the band was made in "channel" form and the hard rubber protected by the side of the channel (fig. 6). In 1913, as an experiment, a "channel base" tire was tried, made to press directly on the S.A.E. (Society of Automotive Engineers) standard wheel without traction plate or staples, previously considered necessary. The experiment was successful, and this new type, being much simpler and less expensive, rapidly superseded all other types in America. In 1915 wide single solid

FIG. 5.—Perspective of solid (European).

tires (fig. 6) were introduced in America (8 in., 10 in., 12 and 14 in. wide) on the rear of heavy trucks in place of dual or twin tires. In 1920 wide singles and duals were almost equal in popularity. The principal development in the period from 1920 to 1925 was the much wider demand for non-skid treads (fig. 6) on solid tires and the development of the cushion tires of the hollow type; that is, having a circumferential cavity extending around the tire inside.

The growth of pneumatic tire production in the United States is shown by the following figures, those for 1913, 1915 and 1925 being estimates:—

|      |            |      |            |
|------|------------|------|------------|
| 1913 | 6,588,000  | 1922 | 40,930,000 |
| 1915 | 12,840,000 | 1923 | 45,245,000 |
| 1920 | 32,400,000 | 1924 | 51,633,000 |
| 1921 | 27,297,000 | 1925 | 53,900,000 |

**Structure, Materials and Manufacture.**—In designing pneumatic tires, five major forms of tire troubles must be kept in mind by the manufacturer: (a) possibility of premature tread wear; (b) breaks in fabric structure; (c) bead troubles; (d) loosening of the tread from the carcass; (e) separation between the plies of cord fabric. The proper resistance to tread wear is provided by using a very high quality of stock as a tread material, combined with suitable thickness and tread pattern. Fabric breaks are guarded against by using a high grade cotton in the cord structure and in suitable quantity so that the factor of safety is at least seven against bursting due to air pressure in the tire. The other three items are functions of the flexing, and to develop further the principles underlying tires, the balloon tire will be taken as an example. Low-pressure air in any tire means a relatively large area of contact. A large area of contact means a greater flattening out (or greater vertical deflection). Flattening out means flexing and working of the carcass, particularly the

FIG. 6.—Perspective of solid (American Giant).

sidewall, a condition which, carried to an extreme, may easily lead to premature failure in circumferential flexing breaks in the sidewall or tread separation or ply separation.

The importance of flexing problems may be seen from the following considerations: For every single revolution of the wheel, the tire carcass from bead to bead and completely around the circumference has to flex, so that if the tire is run soft, the degree of flexing is much more exaggerated than if run properly inflated. A tire which renders 15,000 m. revolves 10,000,000 times. To give this mileage, every part of the carcass must flex 10,000,000 times and not fail. Manifestly, if a great many million flexes must be provided against without failure, the major problem is to prevent excessive flexing and introduce qualities into the tire to make it still more proof against flexing failures.

The component parts of the straight-side pneumatic tire are shown in figs. 7 and 8. The bead portion has been embedded in it a circular inextensible wire core, usually of many strands in the form of braid, cables or coils (to give a certain amount of flexibility). This wire anchors the tire to the rim, prevents it from blowing off, and gives enough rigidity to prevent the tire from creeping on the rim when inflated. The body or "carcass" of the pneumatic tire consists of bias "plies" of cotton fabric impregnated with adhesive rubber "friction," insulated from each other by a thin "skim coat" of the rubber, and having the edges of the plies folded or "tied in" alternately over and round the wire bead core (see fig. 7 showing detail of a typical bead "tie-in"). Since the function of the carcass is to serve as a strong yet flexible container for the inner tube with its charge of compressed air, the specifications covering the fabric call for great strength, uniformity of weight, freedom from grit and the best grades of long staple cotton. "Cord" ply-fabric is primarily a warp composed of parallel cores of combed Arizona high-quality cotton resembling fish line and weighing 11 to 15 oz. per sq. yard. Each cord (23s-5-3), cabled yarn, has a tensile strength of 16 to 20 pounds. In cord tires the cords of each ply must cross those adjacent, consequently the direction of the

bias is reversed in the successive plies. The bead "tie-in" around the rubberised wire bead "core" also includes narrow reinforcing strips of frictioned fabric (see figs. 7 and 8). The outermost of these is named the "chafing" strip. The outside of the carcass is entirely covered with rubber; the sides with a

FIG. 7.—Cross section of straight-side bead on rim.

"sidewall" layer, 1-16 in. thick, and at the tread portion with "cushion stock," "breaker fabric," "undertread" and "tread."

The tread is the thick, tough, firm, wear-resisting face of the tire which is in contact with the road surface. The forces and stresses of vehicle operation are so severe in their tendency to tear the tread from the carcass that the tire makers have found it impracticable to attach the tread directly to the carcass, and have interposed the soft, elastic, adhesive "cushion" and open mesh "breaker fabric" to taper off the severity of the shearing stresses that would loosen the tread. Another very important function of the cushion and breaker is to prevent fabric rupture of the carcass by softening and spreading the intensity of impact of rough roads. The design and quality of the tread rubber must be worked out to wear at least as long as any other part of a balanced tire. The physical properties most desired are toughness, to resist cutting and chipping, and attrition resistance to provide against abrasion from road surface friction.

**Inner Tubes.**—There are no particular differences of design for the inner tubes; nearly all makes resemble each other very closely. Highest quality rubber, with little or no compounding except sulphur, is used for grey tubes (see RUBBER). The best red tubes are compounded with antimony sulphide. To be

FIG. 8.—Perspective of step down section of balloon tire.

satisfactory the tube must hold air; not crack or check in storage; not stretch out of shape; not stick to the casing; not split or tear easily; not be affected by heating; and must be repaired easily. "Flaps," made of inexpensive rubberised fabric, are used in straight-side tires to prevent the tube from being pinched or nipped under the edge of the bead, and to keep water and rim rust away from the tube.

**Manufacturing Processes.**—Only general ideas of manufacturing can be mentioned. First, there is "stock preparation;" the rubber and "compounds" are mixed, the fabrics "frictioned" and "skimcoated" with rubber, gauged to a very exact thickness, the frictioned fabric cut to proper widths on a

machine called the "bias cutter," the cushion, undertread, and sidewall stocks sheeted out and cut to width on the calender, the tread rubber prepared either in the calender or the "tubing" machine, and the bead wires padded with rubber and frictioned fabric and cold pressed into shape (see RUBBER). "Building" the tire is the next step. A "core," in shape and size like the inside of a finished tire used as a building form, is mounted on a stand which permits the core to revolve. The tire plies are drawn taut around the core and rolled down smooth one after another, and at the proper time the bead is put into position. After the last ply is in place, the tie-in at the bead is made; the building is finished by adding the sidewall, cushion, breaker strip and tread. The final step is the vulcanising or "curing." Fundamentally this is simply the process of subjecting the "uncured" tire to pressure in a strong iron "mould" with an inflated "air bag" inside the tire. The heat effects chemical changes in the rubber compounds just as in cooking. Quality in a tire is very dependent on the curing. (See also MOTOR VEHICLES.)

(J. E. H.)\*

**TIROL** (see 26.1010).—The question that arose in 1926 in this area is more properly that of the South Tirol—i.e., Trentino and Alto Adige. The area of Trentino is 2,454 sq. m.; that of Alto Adige (including Ampezzo) 2,953 square miles. By the census figures of 1910 there were in Trentino 13,450 Germans and 360,847 Italians and Ladins. In Alto Adige there were 215,796 Germans and 22,500 Italians and Ladins. There can be no question that the arrangement made in 1866 was intended to give Austria a strategic advantage against Italy. The Trentino projects into Italy, and threatened the plains of Lombardy and Venetia.

*Treaty of London and the Peace Settlement.*—The first Italian demand was made, when Italy was still neutral, in Jan. 1915. Italy formulated her demands on April 8 1915. The line which she desired ran from Monte Cevedale to the northeast, including Bozen (Bolzano), and then followed an irregular line to Cortina

3. By the Treaty of London Italy was promised much more than she had previously claimed. She demanded, and France, Great Britain and Russia consented, that she should receive an area of an average depth of 30 km. to the north up to the Brenner Pass. It included many areas and districts inhabited by a purely German race, and 229,261 Germans in all. Italy claimed this region on purely strategic grounds. At the Peace Conference Austria stood out strictly for the ethnical line, which would have given Italy all the Trentino and a part of the Alto Adige. The principal allied Powers replied that they saw no reason for altering the proposed frontier, adding:—

It results from the very clear declaration made by the president of the council of the Italian Ministers (Signor Tittoni) to the Parliament at Rome that the Italian Govt. proposes to adopt a broadly liberal policy towards its new subjects of German race in what concerns their language, culture and economic interests.

This was on Sept. 2 1919. France and Great Britain were bound by the Treaty of London, but President Wilson was not. He seems to have been unaware of the ethnical facts at the time, and is known to have greatly regretted his decision subsequently. So early as Nov. 12 1919 he took an opportunity of pointing out to Italy that he had, out of his "sincere sympathy for Italy," permitted her to annex in the Tirol "a considerable region populated by alien inhabitants."

*Minorities.*—The question of the protection of the racial culture of Germans in what is now Italian territory is difficult. During 1919 Tittoni gave repeated pledges in public on the subject, and Italy's Allies had publicly affirmed their belief in her sincerity. There was therefore a strong moral pledge given by Italy, and an equally strong moral obligation on her Allies to exhort her to keep it. But it cannot be contended that any question of legal obligation was involved. Had that been so, Italy would have been compelled to sign a minority treaty.

Italian rule began by being liberal, but soon became oppressive. A small but singularly illuminating incident is that of the confiscation without compensation of the entire property of the Austrian Alpine clubs in the new Italian territory. The protests of the Tiroleans were vehement, and not always discreet, but the severity of Italian rule increased as Mussolini developed his power. A violent interchange of speeches took place between the Austrian Govt., Herr Stresemann speaking for Germany, and Mussolini in Feb. 1926. It is not clear that Stresemann's intervention was in order, as Austria is forbidden to unite with Germany by Art. 80 in the Treaty of Versailles (cf. Article 88 of Treaty of St. Germain). Mussolini replied with warmth, and perhaps without adequate respect for the pledges of Tittoni. It would have been open to Great Britain or France to bring the matter up in the Assembly or the Council of the League, under Article 11 of the Covenant.

**TIRPITZ, ALFRED VON**<sup>1</sup> (1849– ), German admiral, was born on March 19 1849 at Küstrin, the son of a high Prussian magistrate, and the descendant of a noble family impoverished by the Thirty Years War. His great grandmother came of a French refugee family named de Sainson. As a boy he was quick, daring and enterprising. He was very capable, but did badly at school. In later years he filled the gaps in his education by industrious private study in languages, history and economics, and by keen observation during his foreign travels. He was an admirer of Treitschke. In 1865 he entered the Prussian navy, the training for which followed the British model. In 1869 he became an officer, in 1888 postcaptain; in 1895 rear-admiral; in 1899 vice-admiral; in 1903 admiral; in 1911 Admiral of the Fleet. In 1897 he became secretary of state for naval affairs, and then, to his regret, had no further chance of practical service at sea. On March 15 1916, for political reasons, he resigned all his offices.

This article like Admiral Scheer's (Vol II. p. 218) is published as written by Admiral Hollweg in accordance with the principle laid down in the footnote thereto.

d'Ampezzo. The Austrians replied by offering the Trentino but excluding Bozen and the Alto Adige. These terms were declined by Italy, which signed the secret Treaty of London with the Entente on April 26 1915, and broke with Austria openly on May

Whilst still a young officer his talents were recognised and suitably employed by the leaders of the German Fleet, General von Stosch and General von Caprivi, and he received exceptional promotion. From his 20th year he was employed only in important positions of organisation or leadership. General von Stosch taught him the need of increasing over-populated Germany's economic and industrial activity, the importance of trade and colonies, the necessity of protecting these interests and making the shipbuilding industry quite independent of foreign help. General von Caprivi initiated him into the system of the duties of the general staff. His creative talents were first utilised when torpedoes developed into an arm suitable for war, in building torpedo boats and in working out a tactical system for their mass employment. His work during this period proved of great value to him later when constructing a fleet of great battleships. Here, and in constructing the fleet, he accomplished model work with a minimum of expense. After practical service at sea as captain, he became chief of staff of the Supreme Naval Command in 1892, and began the preliminary work for his plan of fleet construction by profound studies in the history and practice of naval warfare.

The idea of the offensive use of arms was the guiding note of all Tirpitz's work. His memoranda, designed to educate the naval officers in modern ideas of their profession, fell into British hands and in this way influenced British tactical ideas also. He combined practical operations with model squadrons of useless ships with the elaboration of his tactical ideas. Simultaneously with this went on the transformation of the modern ship of war, with its technical complications, into an apparatus which worked with mechanical perfection. He encouraged the education of crews to independent action in all emergencies. His tactical memorandum, No. 9 (printed in *Nauticus, Jahrbuch für Deutschlands Seeinteressen*, 1926), which sums up everything of basic value in the art of naval warfare, afterwards served him to convince the reluctant Reichstag of the necessity of forming a German fleet according to quite definite laws. Tirpitz himself considered his tactical abilities to be his greatest gift and often regretted that he afterwards no longer exercised decisive influence on the further development of sea tactics. As a statesman, Tirpitz pursued the political aim of securing the growing marine interests of the German people, which had become a great exporting and importing industrial state. For this reason he felt the building of a fleet to be a necessity and no luxury, since it made Germany a more acceptable ally and helped to create a sort of balance of power at sea.

The overwhelming power of Great Britain, the dependence on her and other superior naval powers into which Germany had fallen and which no longer corresponded with her greatness and her vital necessities, the aversion of the Germans from the sea, made a deep impression on him even as a youth, and particularly on his last foreign journey as Admiral of the cruiser squadron, 1895-7. As early as 1871, he spoke of the necessity of a German fleet in a letter to his father. He considered that it was an economic and also a social necessity that the working German people should gain greater independence from all political eventualities. He further saw in Germany the power of the future on which the smaller European powers might lean at sea. In view of the formation of great self-sufficient economic units in the world, he probably considered his ideas to be a consistent continuation of Bismarck's train of thought, and perhaps thought of a kind of economic Pan-Europa under a wise German leadership.

Tirpitz vigorously opposed the suggestion that Germany might annex Holland, one reason being that he was always anxious to spare the small Nordic states. He would also have been prepared to make the Danes concessions in Schleswig in order to win their friendship, and was anxious for Italy to have a considerable fleet. Tirpitz never asked for war and always believed that a war could only interrupt Germany's rise; but was in favour of a German rapprochement with Russia as Bismarck wished it, and of a German-Russian-Japanese understanding. He disapproved also of the German Baghdad policy because it infringed simultaneously on the Russian and British spheres of in-

fluence. He was against irritating America in any way and disapproved both of the German intervention in Manila and of the British German blockade of Venezuela. Moreover he saw clearly that in forming Germany into a sea power he would have to reckon with the opposition of Great Britain. He believed firmly, however, that it must be possible, if Germany proceeded with caution, to pass through the danger zone of the time of fleet construction without war, and that, finally, an honest understanding between Germany and Great Britain could only be advanced if Germany was a real power on sea as on land. Summing up British psychology and British love for everything straight and strong, he reckoned that Germanic England, whose statesmanship and power at sea he rated very highly, would in the end prefer a rapprochement with a strong Germany to any other political combination. It was only unwillingly and with hesitation that he adopted "the idea of risk" aimed at Great Britain in his naval estimate of 1900.

Even after the World War, and even when he had learnt the details of the British policy of encirclement, Tirpitz did not change his opinion that, taking all in all, the rapprochement between Germany and Britain was advanced rather than hindered by the construction of the fleet, and that only the outbreak of the War, which was most unwelcome to him, had prevented the last maturing of his political aims. His naval programme always aimed at leaving Britain a sufficient superiority. He considered that the formula of the respective strengths of three to two suggested by Lloyd George, which Churchill later, although with reservations, altered to 16 to 10 or eight squadrons to five, gave Britain sufficient protection against any aggressive intentions on the part of Germany.

When organising the construction of the German fleet, Tirpitz went through the work very carefully and systematically, as his nature was. Each step was thought out to its last consequences. He refused flatly to construct the greater cruiser fleet which the Emperor was anxious to have when he was appointed Secretary of State, in view of the experience of the past with cruiser warfare and the lack of all foreign bases for Germany. His aim was and remained the formation of a battle fleet. In view of early experience with naval construction programmes in the Reichstag, his naval estimates carefully avoided votes for new constructions of ships which depended on the momentary humour of the deputies. He aimed at securing legal authority for the number of ships of the fleet to be built, for their regular replacement and maintenance. Inevitably a certain stiffness thus came into the naval programme, which was at times a little inconvenient during the critical years.

Tirpitz was always haunted by the fear that his successor would abandon important principles of his programme. He was convinced that the diplomats did not understand the real idea of his programme in the least. The squadron of eight ships as a tactical unit was the base of his naval programme. The first law of 1898 approved a double squadron of ships of the line with the necessary cruisers. The law of 1900 doubled the battle fleet. Supplementary laws of 1904, 1906 and 1908 reduced the maximum age of ships and thereby altered the plan of new construction. The foreign cruiser fleet and the torpedo-boat forces were increased, and account was taken of the British dreadnought programme. The Kiel Canal was widened to take battleships. The supplementary bill which Tirpitz introduced after Agadir in 1912 only increased the number of ships to be constructed by a little, but increased the strength of the active fleet. The supplementary law of 1912 was to be the last bill of the naval programme. The fleet of 1920 was to consist of one flag ship of the fleet, five squadrons of battleships of eight ships each, 12 cruisers for home service, eight large cruisers for foreign service and 40 small cruisers, including 10 for foreign service. Three squadrons of ships of the line with the necessary cruisers were to be always ready as a battle fleet. His construction programme was reduced after the negotiations with Haldane in 1912, and only provided for three new ships to be distributed over several years. Taking 61 great battleships and a life of 20 years, three large ships would be launched regularly every year on this plan.

If Britain had really recognised German sea power, Tirpitz would probably have agreed to some arrangement on the lines of the later Washington agreement of 1922, dealing with the proportionate strength of the two Powers. Tirpitz only became deeply interested in the construction of submarines after the Diesel engines were perfected for service in 1908. The ultimate strength of submarines was then fixed at 72. There was never any idea of mercantile submarine warfare. Tirpitz considered the battle fleet to be the best protection for the extensive German coast line, and spent little money on its fortification. He only modernised Heligoland, and expanded it into a fortified harbour. Parallel with the construction of the fleet, the State wharves were systematically expanded and grew to be industrial implements of the first order.

Tirpitz's relations with the Emperor were peculiar. The Emperor could not do without him to organise the expansion of the fleet, although not really liking his rather stiff but always consistent and never obsequious manner. Tirpitz complied with the particular wishes of the Emperor whenever possible but energetically opposed fantastic plans of naval construction. He often was hampered by William II.'s political ways, and whenever possible put on the brake. But so long as he controlled the construction of the fleet he held firmly to his real aim, in spite of varying political currents. Tirpitz was a convinced Monarchist and remained so after the War. Tsingtao, whose acquisition he had proposed, and whose expansion he wished to control himself, was developed by him into a model colony on the most modern lines. He always considered this lease in China as a bond between German and Chinese culture, never as a base to exploit the Chinese economically.

Up to the outbreak of the World War, Tirpitz enjoyed a steadily increasing popularity in Parliament and with the people. The feelings of German nationality and unity and manly pride in German strength and deeds were encouraged by him. The circle of his real co-workers and colleagues was, however, always small. The number of those who were united to him in personal friendship was even smaller. He was a good judge of men and exploited the special talents of his subordinates ruthlessly. He himself always retained his wide general view and never lost himself in details. In the Corps of Naval Officers his aims were not always fully understood. He probably never revealed his ultimate aims to any of his friends, and, like all great men, was often compelled to stand alone. He was careful to keep up relations with members of Parliament and cultured men, and did much for the journalistic profession. He recognised very early that a good idea needs publicity to be politically effectual. Before the War he exercised but little influence on the activities of the Admiralty staff. Yet he always kept under his own control, in spite of all opposition, the construction of the ships which proved their worth so well in the War. The orders to the fleet and army at the outbreak of War were not known to him. Before the War he purposely paid little attention to the mobilisation plans of the fleet, because he was against war on principle.

In politics Tirpitz seldom played an active part. He knew nothing of the British offer of an alliance at the close of the 19th century. Other details of foreign policy were also concealed from him; and although he offered his advice to the Chancellor von Bethmann Hollweg he was not consulted when important political measures were taken; for example, when the cruiser was sent to Agadir in 1911. At the end of 1911, he could have become Chancellor of the Reich, but he never desired this office. During the critical time of Lord Haldane's visit in 1912, Tirpitz stated that he would have given up his supplementary naval estimate completely for a real neutrality agreement with Britain. He did not entirely approve of the measures taken by the German Govt. after the murder in Sarajevo (1914) and was for avoiding the threatened war at all costs. Tirpitz did not share the opinion that Britain would stand out of the war, and foresaw that the sympathies of America would be on the side of Britain. He was in favour of a short war, and for putting the German Fleet to a decisive battle. He believed that the intervention of America would in any case prevent a complete victory, but

thought that if Germany exercised all her forces, the German Reich could remain a really great power, and at the worst acknowledge defeat whilst her forces were still unexhausted. He was also against any form of annexation but was only anxious lest the Belgian coast should pass into the possession of Britain. In general, he saw the War as the last struggle of freedom against the world capitalism of the Anglo-Saxons.

The part assigned to Tirpitz in the War was unworthy of his abilities. At the beginning he offered to take over the entire control of the navy, including the military control, but this was refused. His position at general headquarters was unsatisfactory; his advice was hardly listened to by the politicians and hardly ever taken. The naval battle for which he wished was not fought. He early recognised the importance of the new U-boats for the issue of the War, but was against employing U-boats too early in the commercial war, and named the spring of 1916 as the right moment. He disapproved of the attitude of the German Govt. during the exchange of Notes with America on the occasion of the sinking of the "Lusitania" and the "Sussex," regarding it as weak. Tirpitz was not implicated in the declaration of U-boat warfare in 1917, and later stated that had he guessed Russia's coming collapse and known of President Wilson's efforts for peace, he would probably have used his influence against U-boat warfare in 1917.

After leaving his post in 1916, Tirpitz entered politics and helped to found the *Vaterlandspartei*, which propagated the will to endure; and after the War had ruined his life's work, he entered the Reichstag in 1921 as German National Deputy. He generally remained in the background in plenary sittings, but owing to his great experience he played an influential part behind the scenes. He spoke in favour of the Dawes Plan and against the Pact of Locarno. In small circles, at official sittings or in the budget commission of the Reichstag, he spoke in a masterly and convincing fashion. In the plenary sittings, he sometimes kept too closely to his preconceived ideas, but created a deep effect by the substance of his speeches.

Tirpitz was not a courtier and found recreation in Saint Blasien in the Black Forest, where he possessed a country house. Four children, two sons and two daughters, were the fruit of his very happy and harmonious marriage with Marie Lipke, who was also his confidante and assistant in his work. His eldest son, a naval officer on the Cruiser "Mainz" was taken prisoner by the British on Aug. 28 1914.

After the War, Tirpitz wrote his recollections, *Erinnerungen* (1918), and was thus one of the first to bring out his memoirs. Both the form and contents of this book make it a very important contribution to contemporary history, although naturally its account is given from the point of view of the author. In order to prevent erroneous conclusions from being drawn from the official German publications and documents which were edited by Tirpitz's political opponents, he issued a second book in the autumn of 1924 *Politische Dokumente; Der Aufbau der Deutschen Weltmacht*. The book is also a contribution from the German point of view to the question of responsibility for the War. It intentionally gives the political opponents of the German naval policy space to state their case at length. The book, in which the author clings stoutly to the correctness of his political ideas, ends with the conclusion that the German people has not shown itself suitable or ripe to rise to be a world power.

See article in Nov. 1925 issue of *Sud-deutsche Monatshefte* on attempts at a naval agreement with Great Britain, and Ulrich von Hassel *Admiral von Tirpitz*. (C. Ho.)

**TISSUE CULTURE.**—The object of tissue culture is the study of the physiology of higher organisms. Within the body of a living animal the relations between tissues and humours cannot be investigated easily because they are too complex. But when tissue cells living in media of known composition are kept under observation like bacteria in pure culture, their fundamental characteristics become apparent. The reciprocal influence of the tissues and of the pericellular fluid can be studied and often expressed quantitatively. In this manner, a new cytological science is being progressively built up.

The method is founded on the possibility of maintaining tissue cells in a condition of active and permanent life outside of the organism. When cells are cultivated, in the proper sense of the word, they multiply, as do bacteria, and synthesise new protoplasm from the constituents of their medium. This condition differs widely from that of survival, where the cells may live and multiply for some time without using the substances contained in the medium. The development of the method has consisted chiefly in the invention of procedures by which pure strains of cells could be isolated and kept in a state of true cultivation indefinitely.

**Early Work.**—The method of cultivating tissues outside of the organism may be considered as the logical development of the investigations of many scientists, such as Cohnheim, Jolly, Leo Loeb and others who have studied with various techniques cells surviving within or without the organism. But it was directly inspired by the beautiful experiments of Harrison, who in 1907 observed the growth of nerve fibres of the frog embryo in a drop of lymph. In 1910 and 1911, other experimenters replaced the lymph with blood plasma, and fragments of adult and embryonic tissues and of tumours of birds and mammals were observed to survive *in vitro* for a few days. At this time it was thought that the cells multiplying in plasma were in a true condition of cultivation. But Lewis found that embryonic cells proliferate as well in saline solution as in plasma. Even in plasma, the mass of the tissues does not increase. By this early technique the tissues were kept in a condition of survival but not of cultivation. It became obvious that no problem of cell physiology could be studied on fresh tissues surviving for a few days in a drop of plasma and subjected to complex influences, such as those of living and dead cells of their own and other types, and of a medium that deteriorated spontaneously within a short time. In 1912, Carrel developed a technique for maintaining a pure strain of fibroblasts in a true state of cultivation. The cells not only survived but synthesised new protoplasm from the constituents of the medium, and the mass of the tissues increased in an unlimited manner. Later, strains of macrophages (1922), of cartilage (1922), of pavement epithelium (1922) and of thyroid (1924) were isolated and kept in pure cultures.

**Techniques.**—The techniques by which a strain of cells can be maintained in a state of true cultivation are far more delicate and difficult than the early procedures, and a thorough apprenticeship is necessary to apply them successfully. The tissues are generally embedded in a coagulum of plasma diluted with tyrode solution and embryonic tissue juice. Proliferation of embryonic tissues takes place as readily in saline solution as in blood serum or plasma. But epithelium and connective tissue do not manufacture new protoplasm when they are cultivated in plasma alone, and, although the cells multiply, the mass of the colonies does not increase. The dividing cells appear to use the substances set free by other cells. When embryonic juice is added to the medium, the building up of protoplasm from the constituents of the nutrient fluid begins immediately. As long as the cells are supplied with embryonic juice, under proper conditions, they synthesise protoplasm. Monocytes behave differently. Cultivated in embryonic tissue juices, they die in a short time. On the contrary, if the medium is composed of diluted serum, they remain alive and spread over large areas. They build up protoplasm from some constituents of serum, while neither fibroblasts nor epithelial cells possess this property. Serum not only fails to supply fibroblasts and epithelial cells with the substances necessary for multiplication, but it inhibits their proliferation and shortens their life *in vitro*. As a rule, the restraining action of serum becomes more pronounced after it has been shaken or heated. The agents that inactivate serum also render it more inhibiting for homologous fibroblasts.

It appears that serum contains certain growth-promoting substances, which are destroyed by shaking and heating, and oppose the inhibiting effect on fibroblasts of other substances that resist heat and shaking. There are in serum two antagonistic groups of substances, the growth-promoting ones always being weaker in their action than the growth-inhibiting. The growth-inhibi-

tion of serum is partly due to the presence of certain lipoids. The nature of the nitrogenous compounds present in embryonic juice and used by epithelial and connective tissue cells in the building up of protoplasm is still unknown. But some of their properties have been studied. Embryonic tissue juice loses its growth-promoting effect after it has been shaken for several hours, or heated at a temperature of 65° C. for a few minutes. The substances that promote cell multiplication are very sensitive to heat. They are partly destroyed at 56° C. in 30 min., and when left in an incubator at 38° C. for 48 hr. their action is greatly weakened. They are also sensitive to the action of radium and X-rays. These substances, used as food material by other cells, are called trephones, from *τρέφω*, *I feed*. They are present in abundance in embryonic tissue, in certain glands of the adult animal and in leucocytes.

**Use of Plasma.**—The plasma is obtained easily from the blood of adult animals such as rabbits, dogs, guinea pigs and chickens, and can be maintained in a fluid condition for a sufficient length of time. After it has been placed in the culture flasks together with the tissues, coagulation is brought about by adding some embryonic juice. The principal constituents of the culture media most generally used are plasma, serum, tyrode solution and embryonic tissue juice, at an hydrogen concentration varying from pH 7.4 to 7.8.

In a fluid containing all the substances necessary for cell multiplication, no growth occurs if the cells do not find the proper support on which to creep. A plasma coagulum, or the surface of a slide covered by a drop of lymph, serum or saline solution, may supply cells with the conditions required for their migration. The finest details of cells spreading on a cover-glass in a saline solution may be observed without difficulty, and this technique is excellent for certain cytological studies. But tissues grow incomparably better and more regularly in a plasma coagulum than in any other medium. Besides, the transfer of the tissues from medium to medium is possible without disturbing the cells embedded in and protected by the fibrin. The cultures are prepared in such a manner that a continuous growth of the tissues becomes possible. The waste products must not be allowed to accumulate in the medium, and the nutrient substances that are unstable and easily destroyed at body temperature must be regularly supplied to the cultures. Two procedures are generally used in order to keep the tissues indefinitely in a condition of constant activity.

The first technique consists in removing the tissue fragment frequently from its medium, washing it in Tyrode solution and transferring it to a fresh medium. The transfer of the tissue takes place every two days. As the nutrient substances contained in the medium do not undergo complete disintegration in 48 hr., and as the accumulation of waste products has but a very slight action on the growth of the tissues during that period of time, the cultures, when transferred from medium to medium, live under practically unchanged conditions.

A second technique has been developed by which the culture medium may be renewed frequently without mechanical disturbance of the tissues or danger of bacterial contamination. Special containers have been made consisting of flat, round flasks with oblique necks. They belong to different types, some being used for measuring the rate of growth of tissues, and the others when cytological examinations are required. The size of the flasks varies from five to eight cm. in diameter, which makes possible the use of large amounts of tissues and medium. By means of special instruments the tissues may be handled conveniently inside the flasks. The principle of the method is to use a medium composed of two parts, one solid and the other fluid, the latter being renewed as often as necessary. The solid medium is composed of coagulated plasma in which the tissues are embedded and which covers the bottom of the flask in a thin layer. The fluid medium, which bathes the solid medium continuously or not as desired, is composed of tyrode solution in which are dissolved the substances to be investigated as to their action on the tissues. The fluid medium diffuses its nutrient principles in the coagulum and also receives the catabolic products of the

tissues. As it may be changed frequently, the tissues grow on the bottom of the flask without being disturbed, in a medium that varies but little in composition. With this technique, epithelial cells, fibroblasts, leucocytes and tumour cells may be observed in a condition of uninterrupted growth for long periods of time.

*Rate of Growth.*—The measurement of the rate of growth is made in the following manner. The slides are placed in a projectoscope, and the outlines of the tissues are drawn immediately after the preparation of the cultures, and after 48 hours' incubation. The areas of the original fragment and of the new growth are measured with a planimeter, and the ratio of the area of the new growth to that of the original fragment is calculated. This relative increase of pure cultures of fibroblasts or epithelium in 48 hr. expresses the rate of growth. The rate of growth, the increase in mass of the tissues in a number of passages and the duration of life of the cultures indicate whether the medium is nutrient, non-nutrient or growth-stimulating without being nutrient. When the tissues are cultivated in large flasks, the increase is measured in the same way and, as the growth is uninterrupted, it may be expressed graphically in a simple manner. The curve expressing the rate of growth of fibroblasts and epithelial cells in a nutrient medium is a parabola. If the medium is non-nutrient, the curve is S-shaped. Modifications in the form of this curve indicate whether the medium contains substances that activate or depress the rate of cell multiplication.

The inherent growth energy of a tissue at a given instant is a function of several independent variables: its growth energy at the preceding instant, and the concentration in the pericellular fluid of the substances that increase or decrease cell activity. It could be ascertained by the activity displayed during an instant by the cells in a medium containing neither activating nor retarding substances, if such a measurement were possible. But the residual energy, which was found to vary at the same time as the inherent energy, may be used as a measurement of the latter. The residual energy is expressed by the duration of life and the proliferative activity of the cells in tyrode solution.

When a sufficient amount of tissue is placed in a flask, it becomes possible to detect the presence of the secretions in the fluid medium. The growth-promoting effect of substances set free by the leucocytes was found in this manner.

The morphology of the tissue cells growing *in vitro* is studied while they are still living. Fragments of the coagulum containing cells are removed from the flasks and placed on ordinary slides. The living unstained cells may be photographed or cinematographed. The use of neutral red, trypan blue, and janus green allows the study of the cytoplasm while the cells are active. The tissues may also be fixed and stained by the ordinary methods.

*Isolation of Pure Strains.*—The isolation and maintenance of pure strains of various types of tissues was an indispensable step in the adaptation of the method of tissue culture to physiological research. The first pure culture of fibroblasts originated over 14 years ago from a fragment of the heart of a chick embryo, and was cultivated in embryonic tissue juice, which was discovered at about the same time to have the property of giving to fibroblasts an unlimited proliferating capacity. Pure strains of fibroblasts can be obtained readily from practically every tissue of fowls, dogs, etc., as connective tissue cells multiply more rapidly than the other cells, which spontaneously disappear within a few weeks. The fibroblasts grow as a dense tissue, which doubles its volume in about 48 hours. The cells are polygonal or spindle-shaped, with long, sharp processes, and with an oval nucleus containing generally two nucleoli. The pure strains of fibroblasts are used especially as a physiological reagent for detecting in serum and other fluids the presence of substances promoting or inhibiting cell multiplication.

Strains of large mononuclears are obtained from cultures of white blood corpuscles. The polymorphonuclear leucocytes, endowed with greater activity, occupy the peripheral area of the culture. The inner zone is covered chiefly with lymphocytes and monocytes. After a few days, the polymorphonuclear leucocytes progressively disappear. They are generally taken up by the lymphocytes and digested. Finally, the mononuclear cells alone

remain, multiply in the medium, and wander through it isolated or in columns, but never aggregate in a tissue. When they accumulate in large numbers, or are packed together by contraction of the medium, they generally die or become transformed into fibroblasts.

Strains of epithelium may be isolated from the iris, the thyroid, the skin and probably from several other tissues. When multiplying on the surface of a plasma clot in a thin layer of embryonic juice, the pavement epithelium derived from the iris assumes the appearance of a continuous membrane. Its rate of growth is slower than that of fibroblasts, and the cultures double in size in about three days. The cells do not dedifferentiate. They grow as a thin mosaic at the surface of the medium and manufacture a large amount of black pigment, similar to that of the cells of the iris. They multiply for many months outside of the organism. Strains of epithelial cells are easily obtained from the thyroid glands of a chick embryo. The cells from a four- or five-month-old strain grow equally well at the surface of the medium or in its depth. They readily digest the fibrin of the coagulum, but multiply at a more rapid rate and are more resistant than pavement epithelium. Sometimes they form acini (grape like clusters) with colloidal material in the centre.

Generally they are more or less irregularly spread in the coagulum, and drops of colloid substances with their characteristic appearance may be seen within the cells or near them in the medium. When pure cultures of fibroblasts are added to thyroid tissue, the fibroblasts soon surround the thyroid epithelium, which organises in a small gland showing acini filled with colloid substance. The inclusion of a fragment of thyroid strain in a pure culture of fibroblasts accelerates the proliferation of the fibroblasts during a number of passages. Pure cultures of fibroblasts and of malignant macrophages are easily isolated from Rous sarcoma. Cartilage cells may be obtained from the pars cartilago sclerae of the eye of chick embryos and cultivated for a long time. The hyaline substance disappears and the small lymphocyte-like cells become transformed into large spindle-shaped cells, which form thin membranes. The rate of growth is slower than that of fibroblasts and epithelium. It is probable that the cells of many other tissues will be obtained in pure cultures.

The method of tissue culture is still in its infancy. But its rapid development and the results already obtained show that it will have an important bearing upon our knowledge of fundamental problems in physiology and pathology.

See A. Fischer, *Tissue Culture* (Copenhagen, 1925); R. Erdmann, *Praktikum der Gewebehilfe oder Explantation besonders der Gewebezucht* (Berlin, 1922).

**TISZA, STEPHEN, COUNT** (1860-1918), Hungarian statesman (see 26.1017).—Tisza only returned to politics after Count Khuen-Hédervary became Prime Minister (Jan. 1910). In the Hungarian Parliament the coalition was still predominant, but it was splitting up and had no hold in the country. Tisza now reorganised the old Liberal party under the name of the National Party of Work with a programme of a return to the strict principles of the compromise of 1867 elaborated by Deak. In the elections of June 1910 this party secured an overwhelming majority, due not so much to traditional governmental oppression and corruption as to Tisza's personal suggestion and unceasing activity. But as the obstruction of the extreme Left against the army legislation could not be stopped by the standing orders of the House, Tisza, considering that the threat of complications in the Balkans made it essential not to weaken the Austro-Hungarian army, took an energetic step. He had himself elected President of the Lower House in 1912, introduced new standing orders, and forced the Army Bill through, ejecting the opposition from the House. A member fired three times at Tisza, who remained calm in his chair. This scene made him very popular. He had to fight some duels with his adversaries, including one with Count Michael Karolyi, which left the two adversaries bitter enemies.

On June 15 1913 Tisza was for the second time nominated Prime Minister. This office gave him the right to control, together with the Austrian Premier, the activity of the common Minister

of Foreign Affairs. In his first memorandum, written after the second Balkan War, he deplores the growth of Serbia and the collapse of Bulgaria, Turkey and later Greece. He further states that Rumania, where public opinion was growing hostile to the dual monarchy, should be assured its territorial integrity, but if it abandoned its alliance, Bulgaria should be brought to bear against it. War should be avoided. In home politics, Tisza was willing to favour such of the non-Hungarian nationalities as would support the State. He attempted to reach an understanding with the leaders of the Transylvanian Rumanians, but without success.

After the murder of the heir to the throne at Sarajevo (June 28 1914) Berchtold proposed a sudden attack on Serbia. Tisza opposed this project in a letter to Francis Joseph (July 1). A week later he again urged his view that diplomatic steps were necessary and a severe ultimatum should be sent, but its conditions should not be impossible to comply with. To avoid the intervention of the Entente, Tisza carried in the Council of Ministers (July 19) that the integrity of Serbia's territory should be respected even if war was to be declared. Though the war against Serbia was declared, he exerted himself for peace by accepting Sir Edward Grey's last proposition (July 31). The Russian general mobilisation marred his endeavours. From that moment he devoted all his energy to the service of his country. He was anxious to miss no opportunity of concluding peace. He was opposed to all German aspirations of territorial aggrandisement and to the introduction of unlimited submarine warfare. When Italy was about to enter the War he offered the chiefs of the opposition seats in the Cabinet to establish a Government of concentration, but met with a refusal.

Apart from foreign politics he had difficulty with the Supreme Command over the extension of its powers to civil affairs; he exerted his influence against military excesses, committed against Hungarian Serbs, and was in frequent conflict with the Austrian Government. He was a true partisan of German Alliance, but he admitted no interference with Hungary's sovereign rights and was strongly opposed to the German idea of an economic "Mittel Europa."

Of truly historic interest was the controversy between him and Conrad von Hötzendorf. In 1915 the armies of the Central Powers were in a very favourable situation. The offensives of their enemies in Italy, Russia and round Arras had been checked; their armies occupied all Poland and Serbia. Conrad declared that Austria's war aims must be the annexation of Poland as far as the Bug, Serbia, Albania and part of Italy. Tisza protested (Dec. 30) against any annexation, on the grounds that the monarchy already possessed too many centrifugal tendencies; he also stated that Belgium should be restored and Serbia be granted lenient peace terms. The monarch adhered to Tisza's opinion. The background of this conflict is still more interesting. Conrad and the greater part of his staff were partisans of Archduke Francis Ferdinand's Magyarophobe policy. They wanted to replace the dualist system, under which Hungary was one of two equal partners in the monarchy, by a federal system dividing the monarchy into five parts under a central Government in Vienna. It was the last struggle between old Austrian tradition, inherited from the Holy Roman Empire and the national kingdom of Hungary.

As long as Francis Joseph lived Tisza's prestige remained unbroken. King Charles, however, was under the influence of Tisza's Austrian and Hungarian enemies. Their rancour was fostered by the participation of Tisza, a Calvinist, with the Primate of Hungary in the act of coronation. The pretext for Tisza's dismissal in June 1917 was his refusal to grant the suffrage to soldiers at the front and his opposition to the demand of the Socialists.

The new Cabinet had but a minority in Parliament. Tisza, now chief of the opposition and in the majority, framed a resolution in which he affirmed the necessity of the German Alliance and pointed out the ambiguous behaviour of the Czechs in the Reichsrath. Finding his position difficult, he went to the front. In the Bukovina and in Italy he commanded a regiment with distinction. Though suffering from dyspepsia, he contented himself with the privates' food; though one-eyed, he was always on the

watch. During this time his only political action was his mission to Croatia and Bosnia (Sept. 1918). Returning to Budapest, he declared (Oct. 17) "We have lost the War," and thus gave the signal for the collapse. He wanted a peace with honour, not a treacherous one. His last two weeks he spent in attempting to unite the different parties; he was even ready to accept Karolyi's leadership in order to save the country and to procure a good peace. Too proud and too conscientious to allow the publication of his pacific endeavours, he was set as a mark for the defeatist soldiers and the mob. Though warned of his grave danger, he remained in Budapest, working until his last moment to unite the historical parties. He was killed by soldiers on Oct. 31 1918, the first day of Count Karolyi's revolution, probably by order of the soldiers' council. His last words were, "It had to be."

Tisza evolved slowly. A party man in his first administration and in his struggle against obstruction, only the immense work and the responsibility put on him by the World War made him a statesman. He had much in common with Bismarck, unlike whom, however, he was a true Liberal, but he did not realise the rapid increase of social democracy due to war industry. Even in politics his tragedy was to be more of a knight than of a diplomatist. Full of animal spirits, he could not always master his temperament. But he was, and, as his memory lives, he is, the finest representative of the old Magyar spirit. See Istvan Tisza, *Osszes Munke*, 2 vol., 1925 (Personal Recollections, letters June to end of Dec. 1914, pub. by the Hungarian Academy). (H. Ma.)

**TITANIC, LOSS OF THE.**—At 2:20 A.M. on April 15 1912, the White Star liner "Titanic," at that time the largest ship afloat, on her maiden voyage, went to the bottom of the Atlantic in lat. 41° 46' N., long. 50° 14' W., about 2½ h. after striking at full speed on an iceberg, with a loss of 1,513 souls out of 2,224 on board.<sup>1</sup> The full record of the disaster is contained in the reports of the inquiries held at once in America by a committee of Congress under Senator Smith, and later in London by a special commission presided over by Lord Mersey (report issued July 30). Painful and difficult though it was to distribute blame in such a case, there could be little doubt that the loss of life—817 passengers out of 1,316, and 696 out of a crew of 908—was much greater than ought to have been possible. Capt. E. J. Smith (b. 1853), a highly experienced seaman, who had been for 38 years in the service of the White Star Co. and who now went down with his ship, seems to have been averse from taking steps at first which might cause a panic on board. A natural expectation of security had been engendered, alike among the owners, officers and passengers of these magnificently appointed liners, which, until a crisis actually came, had made it almost unthinkable that it could come with such suddenness; but the fact remains that responsibility for the lives of passengers rests with those who control the ship.

In this case, it was not the inadequacy of the physical means of escape that accounted for the large proportion of the lost who remained on board; it was the inadequate organisation for purposes of using them and inadequate information as to the necessity. Apart from that, both Great Britain and America could mingle sorrow and pride over many fine incidents of the tragedy. The figures of the 711 saved by the "Carpathia" (including about 60 who were picked up in the boats after the ship went down) speak for themselves: Women: first class, 140 out of 144; second class, 80 out of 93; third class, 76 out of 105; crew, 20 out of 23. Children: first class, 6 out of 6; second class, 24 out of 24; third class, 27 out of 79. Men: first class, 57 out of 175; second class, 14 out of 168; third class, 75 out of 462; crew 192 out of 885. Altogether the percentage of women saved was 74·35, of children 52·29, of men 20·27. The comparatively small proportion of third-class passengers saved was shown to be purely accidental and not due to any preference being deliberately given to others; they were handicapped, however, by their quarters being remote from the boat deck, and by so many of them being unable to speak or understand English.

See British Parliamentary Papers: No. 2253, *Shipping Casualties (Titanic)*, 1912 (cd. 6352).

<sup>1</sup>The exact figures remained doubtful, but those given are from Lord Mersey's report.

**TITTONI, TOMMASO** (1855– ), Italian politician, was born in Rome and educated at Naples, Oxford and Liège. In 1886 he was elected deputy for Civitavecchia and in 1902 was raised to the Senate. He was Foreign Minister for the second Giolitti Cabinet (1903), and in this capacity he aimed at improving relations with Austria. On the resignation of Giolitti in March 1905, Tittoni became interim premier for a few days and remained in the Fortis Cabinet as Foreign Minister. His proposed reduction of the duty on Spanish wines in connection with an Italo-Spanish commercial treaty aroused much indignation and caused the fall of the Cabinet on Dec. 24 1905. In March 1906 he was appointed ambassador in London, but on the return of Giolitti to power in May, he returned to the *Consulta*, and there continued the policy of improving relations with Austria. In April 1910 he was appointed ambassador in Paris. When the World War broke out, in spite of his Triplicist policy, he openly expressed himself in favour of Italian neutrality. In Nov. 1916 he resigned from the Paris Embassy. In June 1919 Nitti chose Tittoni as Foreign Minister and first delegate at the Peace Conference, but he was forced to resign owing to ill-health in November. He was chosen president of the Senate in Dec. and was later appointed Italian delegate on the Council and Assembly of the League of Nations, but ill-health again forced him to relinquish the latter appointment. On the advent to power of Fascism he supported the new Government, without joining the Fascist party.

**TOBACCO** (see 26.1035).—During the period 1910–25 the world production of tobacco greatly increased. The production for the year 1923 was about 3,977 million lb. as against an annual average of about 3,000 million lb. for the years 1909–13. The following table shows the area under tobacco and the production of the chief producing countries in 1909–13 (annual average), 1914–8 (annual average) and 1924, according to the *International Year Book of Agricultural Statistics*:—

| Country.          | Area (hectares) |                |         | Production (quintals) |                |           |
|-------------------|-----------------|----------------|---------|-----------------------|----------------|-----------|
|                   | Average 1909–13 | Average 1914–8 | 1924    | Average 1909–13       | Average 1914–8 | 1924      |
| Germany           | 15,709          | 11,365         | 16,252  | 301,805               | 257,625        | 142,525   |
| Bulgaria          | 8,094           | 24,489         | 46,955  | 62,856                | 167,623        | 436,975   |
| France            | 14,873          | 10,458         | 12,791  | 205,354               | 154,713        | 244,301   |
| Yugoslavia        | 2,411           | 3              | 35,230  | 16,960                | 3              | 356,851   |
| Greece            | 15,466          | 33,756         | 60,049  | 127,103               | 224,107        | 494,151   |
| Italy             | 8,072           | 6,611          | 33,800  | 100,699               | 86,200         | 413,250   |
| Hungary           | 49,047          | 45,579         | 15,482  | 665,091               | 507,724        | 172,573   |
| Russia in Europe  | 55,836          | 54,432         | 3       | 930,851               | 903,433        | 3         |
| United States     | 495,017         | 580,487        | 696,067 | 4,518,553             | 5,387,326      | 5,636,414 |
| British India     | 423,815         | 434,896        | 539,070 | 3                     | 3              | 3         |
| Japan             | 29,301          | 29,142         | 37,686  | 425,095               | 463,256        | 562,500   |
| Philippines       | 62,167          | 62,673         | 72,000  | 294,857               | 473,315        | 433,230   |
| Russia in Asia    | 14,804          | 20,261         | 3       | 140,338               | 174,387        | 3         |
| Algeria           | 10,170          | 11,710         | 20,572  | 106,237               | 129,385        | 300,000   |
| Dutch East Indies | 162,135         | 166,543        | 167,488 | 635,666               | 530,758        | 248,400   |
| Cuba              | 3               | 3              | 3       | 334,148               | 285,807        | 181,000   |
| Brazil            | 3               | 3              | 78,774  | 3                     | 450,000        | 595,504   |

<sup>1</sup> 1923. <sup>2</sup> From cultivation by Europeans only. <sup>3</sup> Not given.

**The Americas.**—The United States retained its position during 1910–25 as the chief tobacco producing country in the world. The tobacco industry made considerable progress, and, although the output of cigars varied but little, the output of cigarettes increased tenfold to over 75 billion in 1925. Exports of leaf tobacco increased from 388,284,000 lb. for the annual average of 1910–4 to 546,257,000 lb. in 1924. Tobacco is the second crop in Cuba and its cultivation is rapidly extending. The extra import duties imposed on cigars by the United Kingdom had an adverse effect upon Cuba's export trade to that country and resulted in the United States replacing the United Kingdom as the chief market for Cuban cigars; the total value of tobacco consumed in and ex-

ported from Cuba in 1924 was \$82,289,686. The cigars of Mexico are second only to those of Cuba, and Mexican tobacco culture is making rapid progress. In Argentina during the post-War period, experiments were made with the cultivation of many varieties of tobacco, and favourable results were obtained. In Santo-Domingo, Porto Rico and the Central American republics the tobacco crop is of considerable importance. Brazil is an important source of world supply, exporting over 70,000,000 lb. annually from 1921 to 1925.

**British Empire.**—Special attention is being devoted in Canada to the extension of tobacco cultivation. The area under tobacco greatly increased during the post-War period, exports of leaf tobacco, mostly to the United Kingdom, increasing from 200,153 lb. in 1921 to over 3,500,000 lb. in 1925. The West Indies, Nyasaland Protectorate, Rhodesia, Kenya, Uganda, Tanganyika, the Union of South Africa, North Borneo, British India and Palestine are paying particular attention to the development of their export trade, which is greatly helped by its preferential import duties granted to Empire from tobacco by the United Kingdom, which is one of the chief world markets for tobacco. Exports from Nyasaland increased from 14,000 lb. in 1902 to over 7,000,000 lb. in 1924. In Southern Rhodesia, tobacco production is a well-established industry, the average annual crop from 1920 was approximately 3,000,000 lb. Northern Rhodesia produced 813,033 lb. of Virginia and 8,152 lb. of Turkish tobacco in 1922–3. South Africa exports of tobacco increased from an annual average of 175,896 lb. for the period 1910–4 to 2,312,284 lb. in 1923. In India the area under tobacco increased by some 25% between 1910 and 1925. Exports, principally to the United Kingdom, Belgium, Germany and Holland, increased greatly during the post-War period, rising from under 4,500,000 lb. in 1922–3 to over 14,500,000 lb. in 1924–5. Export of cigars from Jamaica in 1924 totalled 88,245 lb. Production in British East Africa and Palestine is of growing importance.

**Europe.**—Climatic conditions in the south of the Balkans are very favourable to the cultivation of tobacco. Bulgaria became prominent as a tobacco producing country after 1913, when, by the Treaty of Bucharest, she obtained possession of tobacco-producing areas of Xanthé, Kirdjali, etc. Her output rapidly increased and good markets were found during the World War in Central Europe. After the end of the War, in spite of the cession of the Xanthé area to Greece, progress was maintained and production steadily increased. Greek production, stimulated by the great influx of refugees from Asia Minor after 1921, rapidly increased. Hungary was very prominent as a European source of tobacco before and during the War, but the surrender of large areas after the War resulted in a great decrease in her output, and a corresponding increase in the output of Yugoslavia and Rumania, who obtained possession of the surrendered districts.

Considerable progress was made during and after the War in tobacco cultivation in Italy, and her output more than doubled between 1921 and 1924. After 1918 Czechoslovakia joined the list of tobacco-producing countries; considerable assistance was given to the industry by the Ministry of Agriculture and experimental stations were established. The output of both Germany and France fell during the War: in the case of Germany the fall continued after 1918, owing to the loss of Alsace; but France, with the addition of the Alsatian output, soon exceeded her pre-War production. French needs during the War resulted in the increase of cultivation in Algeria, whose output increased threefold between 1910 and 1924. Russian production in 1923 was only some 40% of the pre-War figure.

**Other Areas.**—The loss of her European territory caused a serious decrease in the Turkish output, but during the post-War period the Anatolian crop increased from an annual average of some 50,000,000 lb. for 1919–22 to over 150,000,000 lb. in 1925; this great increase was partly due to the influx of Turkish refugees from Macedonia, but mainly to more stable political conditions. China, Japan, the Philippines and the Dutch East Indies retained their importance as tobacco producing areas: the Japanese output showed a considerable increase between 1910 and 1924.

**TOGO** (see 26.1046).—This German colony in West Africa was conquered in the first month of the World War (Aug. 1914) by a British force, from the Gold Coast under Capt. (temp. Lieut.-Col.) F. C. Poryant, aided by detachments sent by the French from Dahomey. Before surrendering, the Germans blew up the powerful wireless station at Atakpame, which had been completed a little earlier in the year. Thereafter the western part, including Lome, the chief port, was administered by the British and the eastern part by the French. In May 1919 the Supreme Council gave the mandate for Togo to Great Britain and France. The first division, made in an Anglo-French agreement of July 10 1919, gave dissatisfaction to French colonial circles, as it left Lome to Great Britain, and by a convention of Sept. 30 1920, in exchange for an enlarged British area in the interior, Lome and the whole

as if it formed part of the Gold Coast Colony. Cocoa, cotton, kola nuts and maize are cultivated, and there are large herds of cattle in the north, but the chief exports are palm oil and palm kernels. The division of Togo left the whole railway system in the French sphere and, although a motor ferry over the Volta at Senchi connects the southern British section with the road system of the Gold Coast, the railway from Palime to Lome, which runs close to the border of the British sphere, takes a large part of the trade. For the year ending March 31 1924 exports were valued at £115,000 (cocoa £99,510) and imports at £22,800. For the same period revenue was £20,000 and expenditure £49,000. Deficits are made good by the Gold Coast.

**French Sphere.**—The French sphere—area 21,893 sq. m.; pop. (1923) 698,340, of whom 210 were whites—adjoins Dahomey, but is administered as a separate entity, the chief official being styled commissioner. He is aided by a council on which non-officials, including one native, have seats. Lome, the capital (pop. 9,400) is the centre for trade. The chief products and exports are the same as in the British sphere. The area under cocoa and cotton is increasing. In 1922 the exports were valued at 17,197,000 francs, the imports at 10,107,000 francs; the budget for 1923 balanced at 8,123,000 francs. Up to 1926 there had been no addition to the railway system left by the Germans in 1914.

See Reports of the French Govt. on Togoland (annual); *Official Reports on the British Sphere in Togoland* (annual, London); *Togoland Handbook* (H. M. Stationery Office, London 1920); *Draft Mandate for Togoland* (cmd. 1350 of 1921). (F. R. C.)

**TOKUGAWA, YOSHINOBU**, PRINCE (1837–1913), Japanese statesman, was born Sept. 29 1837 at Tōkyō. He was the last of the Tokugawa Govt. (see 26.1047), succeeding Shogun the 14th Shogun, Iemochi, in 1866. Realising after a year's time that the proper government of the country was impossible on the lines of feudalism, which was a bar to all progress and a source of continual internal strife, the Shogun handed his resignation to the emperor on Oct. 14 1867. This act of sacrifice was the prelude to the enlightened Meiji era, which dates from the beginning of 1868. Tokugawa, having renounced his shogunate rights, went into a strict retirement from which he never emerged. He even renounced the succession to his title for his direct heir in favour of a collateral branch of the family, the first to inherit the title being Prince Iyesato Tokugawa, for many years president of the House of Peers. The Emperor Meiji accepted the renunciation, but he conferred on him another title of prince to be bequeathed to his son. He died Nov. 21 1913 at Tōkyō.

**TOKUTOMI, IICHIRO** (1863– ), Japanese journalist and author, was born at Kumamoto in Jan. 1863 and educated at the Doshisha, Kyoto. In 1887 he issued a monthly magazine, *The Friend of the Nation*, and in 1890 started in Tōkyō, the daily *Kokumin Shimbun* (Nation), of which he was proprietor and editor. He also began to issue in the same year *The Far East*, an English monthly. Tokutomi, who was appointed a crown member of the House of Peers in 1911, published many important political and historical works including *The Future Japan* (1886) and *History of Modern Japan*, not yet complete. In 1924 the Imperial Japanese Academy awarded him the Emperor's Medal in recognition of the merit of his works on Japanese history.

**TŌKYŌ**, Japan (see 26.1047), had in 1923 a population of 2,478,233, but in Sept. of that year a disastrous earthquake and a fire which followed reduced the population by death and migration to 1,529,616. From being the fifth largest city in the world, Tōkyō fell to the 10th place. The damage was enormous, though the destruction was not as complete as at Yokohama; the railway station and the Imperial Hotel escaped. An area of nearly 25 sq. m. was burnt, and between 60,000 and 70,000 people killed, many of them in a big clothing factory. The water pipes were broken, which made it impossible to check the conflagration which followed the shock, and 80% of the numerous bridges were destroyed. Reconstruction was begun at once, and very large sums were given to relief funds. Tents were first put up for the survivors and the unburnt portions of buildings rendered habitable, and later large barracks were erected, which housed great numbers, living on charity and Government

seaboard except 32 m. went to France. Both spheres are governed under mandates approved by the Council of the League of Nations on July 20 1922, and, in each, citizens of the United States have obtained the right to equal treatment with nationals of the members of the League.

**British Sphere.**—The British sphere, which adjoins the Gold Coast, has an area of 13,040 sq. m. and a pop. (1921 census) of 187,959, of these, 9,652 were Christians and 5,678 Moslems; in 1924 the European residents numbered 27. The sphere is divided into two sections, the northern being administered as if it formed part of the Northern Territories of the Gold Coast, the southern

relief, for many months. The streets were soon lined with temporary shops and huts.

Before the earthquake Tōkyō had many narrow alleys and slum areas, and after the disaster an elaborate plan was prepared, embodying wider roads, many open spaces, new thoroughfares and the consolidation of the city under a central authority. The work of clearing the ruins, of re-establishing communications, and of reconstruction proceeded with wonderful rapidity, and by June 1924 about 80% of the houses in the city before the earthquake were replaced by temporary erections. The town plan, however, was largely ignored, since it involved the displacement of many thousands of these temporary homes, and the voluntary cession by a number of the inhabitants of a portion of their land for purposes of road widening. The approach to the Imperial Museum, however, has been nearly doubled in width, and the schools have been rebuilt with large playgrounds, which will serve as refuges in case of fire. The new buildings are either large concrete or small wooden erections. Two big department stores have been built on the Ginza. The Shimbashi bridge was reopened in 1925 and the Russian cathedral is being rebuilt. The new Parliament buildings were destroyed by fire in Sept. 1925, and a temporary building was erected for the winter session. The electric railway has been reconstructed as a circular line; the line to Yokohama was electrified and double-tracked in 1915. No sewage system has been undertaken, and the large programme of port improvements, planned in 1920, had not been begun in 1924. In 1925 Rockefeller gave £400,000 to the Imperial University library, and many books have also been sent from Great Britain. An art gallery, planned before the earthquake, was begun in 1924.

**TOKYŌ, UNIVERSITY OF** (see 15.221).—Imperial Ordinances, 388 (Dec. 5 1918), 12, 13 and 14 (Feb. 6 1919), 50 (March 31 1919), 409 and 411 (Aug. 20 1919), 408 (Sept. 16 1920), 310 (July 9 1921), regulate the constitution of the university, its officers and chairs. Other ordinances deal with the institution of chairs of which there were 255 in 1923, distributed as follows: faculty of law, 32; faculty of medicine, 33; faculty of engineering, 57; faculty of letters, 39; faculty of science, 39; faculty of agriculture, 39 and faculty of economics, 16. The university is closely associated with the committee for the compilation of a national history and geographical records. The Tōkyō Astronomical Observatory is attached directly to the university. The Government appropriation for the university was stated at yen 2,984,805 by Law No. 8 on March 27 1922.

**TOLEDO, Ohio, U.S.A.** (see 26.1051), enlarged its area to 35.55 sq. m. by 1925. The population increased 44.3% in the decade after 1910, reaching 243,164 in 1920, of whom 38,296 were foreign-born and 5,691 were negroes (an increase of 203.2%); and in 1925 (census bureau estimate) 287,380. The output of the diversified industries within the city limits was valued at \$61,230,000 in 1909; \$293,521,000 in 1919; \$360,375,095 in 1923. Receipts and shipments by water, including both foreign and domestic commerce, amounted in 1923 to 2,547,000 and 9,441,000 net tons respectively, the tonnage of shipments ranking second only to that of Duluth-Superior among the Lake Ports. In 1925 the coal loaded on vessels amounted to 14,010,000 tons, and the freight-car movement totalled 5,747,900 cars. Building permits in the five years 1920-4 represented a value of \$55,844,000. The assessed valuation of property in 1925 was \$560,000,000. In addition to 18 steam railways and nine inter-urban electric lines, by 1925 there were nine inter-urban bus lines entering the city. The local transit system, owned by the Community Traction Co., was operated under a service-at-cost franchise, with clauses reserving to the city the right to acquire ownership.

A new city charter was adopted in 1914, providing for the election by popular vote on a non-partisan ballot of a mayor (with extensive appointing powers), a vice-mayor, 20 councilmen, and the five members of the Board of Education. The City Plan Commission, created by this charter, was organised in 1916, and as soon as funds were available proceeded to prepare (1922-4) a comprehensive plan, with many and important improvements. By 1925 the public-school system included 55 elementary and 4

high schools; the University of Toledo (supported by the city) had about 1,600 matriculated students; the total park area had been increased to 1,401 acres. Toledo has a low general death-rate; a low infant mortality; a relatively small amount of illiteracy and of child labour; and a high proportion (49.4%) of home ownership.

**TOLLER, ERNST** (1893—), German poet, was born at Samotschin, on Dec. 1 1893. On the outbreak of the World War he joined the army as a volunteer, but became ill and thereupon devoted himself to study. He was a socialist, and a friend of Eisner, and in 1918 became President of the Munich section of the German Independent Socialist party. He commanded the Red Guard in Dachau during the Soviet régime in Munich (April 1919). In July 1919 he was tried for high treason and sentenced to five years imprisonment in a fortress. Toller is the dramatist of the Revolution. His works, which are strongly coloured by his political ideas, include *Die Wandlung* (1920); *Masse Mensch* (1921, Eng. tr. 1923); *Die Maschinenstürmer* (1922, Eng. tr. 1923); *Hinkemann* (1924); also two choral works, *Der Tag des Proletariats*, *Requiem den erschossenen Brüdern*; two volumes of poetry, *Gedichte der Gefangenen*, and *Das Schwalbenbuch* (1924, also Eng. tr.) A grotesque comedy *Der entfesselte Wotan*, and the puppet play *Die Rache des verhöhlten Liebhabers* (1925) stand apart from this politically coloured sphere of thought. See Stefan Grossmann, *Der Hochverräter Ernst Toller* (1919).

**TOMSKY**, pseudonym of Michael Pavlovich Efremov (1880—), Russian politician, born Oct. 19 1880 in St. Petersburg (Leningrad), was the son of a workman, and became a factory hand at the age of 12, specialising later as a skilled chromolithographer. In 1904 he joined the Bolshevik section of the Russian Social Democratic party and was a member of the Reval Council of Workers' Deputies during the revolution of 1905. Between 1906 and 1917 Tomskey was an active member of the St. Petersburg and Moscow secret committees of the Bolshevik party, edited an illegal party paper *The Worker's Flag*, suffered various terms of imprisonment and deportation and was finally sentenced to five years' hard labour in the Moscow Butyrka prison, followed by deportation for life to Siberia. Released by the March revolution of 1917, Tomskey took part in the Bolshevik July rising in St. Petersburg and the Nov. revolution in Moscow. Afterwards he devoted himself particularly to trade union work, and edited *The Metal Workers' Review*. He was elected member of the Moscow trade union council and in 1918 became President of the All-Russian central trade union council, with a short interval when he acted as representative of the Soviets in Turkestan. On the reorganisation of the Russian Soviet Federation of Socialist Republics into the Union of the Soviet Socialist Republic he became a member of the Central Executive Committee of the U.S.S.R.

Tomskey also took an active part in the diplomatic work of Soviet Russia and was vice-president of the Soviet delegation to London in 1924 and one of the signatories to the treaty ratified by the British Labour Government. In March 1926 he was appointed one of the delegates to Paris in the negotiations with France. He acted as general secretary of the provisional international council of the trade unions from its formation on Aug. 1 1920 to May 1921, and addressed the British trade unions at the conferences at Hull (Sept. 1924) and Scarborough (Sept. 1925).

His most important writings and addresses are included in the following volumes: *Die Neuen Aufgaben der russischen Gewerkschaften* (1922); *Der gegenwärtige Stand der Gewerkschaftsbewegung in Russland* (1923); *Getting Together: Speeches Delivered in Russia and England: 1924-25* (1925).

**TÖNISSON, JAAN** (1868—), Estonian nationalist leader, was the son of a farmer in the Viljandi district of Livonia. After graduating in law at the University of Dorpat (Tartu) he was for some years in the judicial service of the Russian Imperial Govt., but quitted it in 1896 to become editor of *Postimees* (*The Postilion*), the oldest Estonian daily newspaper in Dorpat. Thenceforward he took an active part in the Estonian national movement. This, dating from the middle of the 19th

century when the first collections of Estonian folklore were made, had been greatly intensified during the agrarian struggle against the German-Baltic nobility. At first the national movement enjoyed the countenance of the Russian authorities who saw in it a useful counterpoise to the Germanism of the ruling classes of the Baltic provinces. Later, however, a compromise was arrived at with the Baltic barons by which the Estonians were saved from being Germanised only to be submitted to a process of Russification. At this crisis in the national movement Tõnisson took a line independent of both German and Russian political influences and endeavoured to concentrate the activities of the Estonian people upon work in the economic and cultural spheres. In the revolution of 1905 he was at the head of the Estonian moderate constitutional movement, which he likewise represented in the Russian Duma, where he attached himself to the Russian Cadet Party, and to the non-Russian element. With the other signatories to the Wiborg Appeal, he was sentenced to three years' imprisonment and loss of political rights.

From 1917 onwards Tõnisson, as leader of the Estonian People's Party, was a member of all the representative bodies of the Estonian people. In the winter of the same year, after he had been expelled by the Bolsheviks, he was associated in Stockholm with the representatives of the Allied Powers in connection with the independence of Estonia, and with them carried through the preliminaries of a *de facto* recognition. From 1919-20 he was Prime Minister, and during his period of office peace was concluded with Russia. In the second Riigikogu (Parliament) he brought about an alliance between his own party and the Christian People's Party and the National Liberals, so as to form a democratic "bloc," which was strong enough to secure his election as president of the Chamber.

**TÖNNIES, FERDINAND** (1855- ), German economist and sociologist, born July 26 1855 in Oldensworth, Schleswig, began to teach at Kiel in 1881, and from 1908-16 was professor there. In 1902 he was made chairman of the German Sociological Society.

His principal works are:—*Gemeinschaft und Gesellschaft* (1887, 5th ed. 1922); *Thomas Hobbes, der Mann und der Denker* (Leipzig, 1922); *Der Nietzsche Kultus* (Leipzig, 1897); *Schiller als Zeitsbürger und Politiker* (1905); *Entwicklung der sozialen Frage* (1907); *Die Sitten* (1909); *Englische Weltpolitik in englischer Beleuchtung* (1915); *Der englische Staat und der deutsche Staat* (1917); *Die Niederländische Uebersee-Trust-Gesellschaft* (Jena, 1916); *Weltkrieg und Völkerrecht* (1917); *Menschheit und Volk* (1918); *Marx's Leben und Lehre* (Jena, 1921); *Kritik der öffentlichen Meinung* (1922).

**TONSILS:** see EAR, NOSE AND THROAT, DISEASES OF.

**TORONTO** (see 27.52), the chief city of Ontario, Canada, and the second city in the Dominion, had a population, predominantly British, of 521,893 in 1921, and an area of 32½ square miles. The death rate was only 10.5 per 1,000 in 1922. Buildings erected since 1911 include Government House, overlooking the Don valley; the fine Anglican church of St. Paul's; the Timothy Eaton memorial church (Methodist); the Prince Edward Viaduct, from Sherbourne street to Danforth avenue; and big office buildings for the Royal Bank of Canada and the Canadian Pacific railway. A similar building, in course of construction for the Canadian National railways in 1925, was said to be the highest in the British Empire. A new joint railway station for the Canadian National and Canadian Pacific systems has been built near the harbour, to replace the old inconvenient joint station, but the transference was somewhat delayed by difficulty in adjusting the railway tracks to a level well above that of the harbour front.

An art museum and college have been opened in the Grange, an interesting old house, formerly the home of Goldwin Smith, and Trinity College has been sold to the city. A scheme has been brought out for the construction of a 33-m. boulevard, which would encircle the city, and 30 m. of internal driveways. Over 12,000 buildings were erected yearly in 1923-5; there are 336 churches and 1,472 ac. of parks and playgrounds. There are two radial electric railways, and in 1921 the municipality took over the tramway system. It was extended, and in 1923 had 222 m. of track. The city's War memorial, in front of the city hall,

was unveiled in 1925, and there is also one to men of the 48th Highlanders in Queen's Park.

*Improved Shipping Facilities.*—The deepening of the Welland canal is expected to bring the larger vessels plying on the Great Lakes to Toronto. A large scheme of harbour improvements has been in progress since 1917 under the Toronto harbour commissioners, and will provide accommodation for over 100 vessels of 5,000 to 10,000 tons when completed. The whole harbour is to be deepened to 30 ft.; a ship canal, retaining walls, and piers and slips across the whole front of the inner harbour, are being built. Reclamations of land are being made between these and the old shore line, on the lake front to the east and west of Toronto, and on Toronto Island. The Eastern Harbour Terminals (formerly Ashbridge Bay), 1½ m. from the centre of the city, and connected with the inner harbour by a ship canal, is being developed as an industrial centre on an area of reclaimed land. In 1924, 477 ac. had been reclaimed, 2½ m. of paved streets made, and 15 m. of railway built. At the Central Harbour Terminals, intended for lighter manufactures and warehousing, 139 ac. of marsh had been reclaimed behind the 2½ m. of wharriage in 1924, and Fleet street had been extended. Toronto has a larger number of industrial establishments than any other Canadian city, and the bank clearances exceeded those of Montreal for the first time in 1923. The annual exhibition, which is held in grounds of 264 ac. is the largest in North America. The hydroelectric system, deriving power from the falls of Niagara, is one of the largest municipal supply undertakings on the American continent. The tendency to centralise the wholesale business of the province in Toronto has been accentuated by the development of mining and lumbering in Northern Ontario. Toronto is the chief livestock market of Canada, and a winter fair, for cattle, etc., was established in 1922. Helium gas was discovered 40 m. from the city in 1925.

**TORONTO, UNIVERSITY OF** (see 27.52).—While in some respects the University of Toronto follows what is called the Oxford type, it has developed independently and with vigour, and as a teaching university occupies a very high position. The four colleges of the university, the Federated and Affiliated Colleges, form a very strong group of educational institutions. In 1923-4 \$1,148,901.20 was received on behalf of the faculty of medicine from the Rockefeller Foundation. For a school of hygiene and for the development of the department, the International Health Board of the Rockefeller Foundation gave \$650,000 and the E. C. Whitney Bequest amounted to \$400,000. There were 4,859 students registered and the enrolment for the university extension classes was 2,560.

The university has benefited largely by gifts, and in recent years a University Press and an electrical engineering building have been erected, and a faculty of music, a school of engineering research, and a department of social service inaugurated. An insulin division of the Connaught laboratories was organised in a building on the campus, previously occupied by the Y.M.C.A., in 1922. A school of public health is to be opened and a building for the study of forestry erected. Hart House, a magnificent building presented for the social and athletic use of the men students, was finished in 1919; the beautiful tower is a War memorial, and contains records, pictures, etc. of the work of the University during the War. Queen's Park house was given as a social centre and hostel for women students in 1925.

**TORPEDO** (see 27.53).—In the World War of 1914-8 the torpedo played a most important part, especially as employed by the German submarines during the submarine campaign. Apart from the use of the torpedo by capital ships, light cruisers, torpedo boat destroyers, submarines and coastal motor boats, torpedoes are also carried by flying machines specially constructed for the purpose. The torpedoes are carried slung under the fuselage, and released at the will of the observer.

During the War a number of specially adapted vessels were fitted to carry torpedo planes, their construction enabling the machines to "take off" and "alight" on the flying deck (see AIRCRAFT CARRIERS; SEAPLANE). Coastal motor boats, small-vessels of great speed were also used for the discharge of torpedoes.

**Construction.**—In the British Navy 21 in. and 18 in. torpedoes are carried, the former by capital ships, light cruisers and destroyers, and the latter by submarines, coastal motor boats and aircraft. The torpedo is divided into six compartments viz., head, air vessel, balance chamber, engine room, buoyancy chamber and tail. These may be described as follows:—

There are two types, the war head containing the explosive, and the collision head used for practice. The former carries a charge of high explosive which is detonated on contact by a device known as the pistol. The collision head used for practice is a steel shell partially filled with cork to ensure buoyancy—it is brought up to approximately war head weight by filling it with water. On impact with target the forepart collapses, thereby lessening the blow on the target and shock to the torpedo itself. To facilitate recovery an indicating light is fitted in a pocket in the head, consisting of phosphide of calcium which on contact with water spontaneously bursts into flame, indicating position of torpedo at the end of the run.

The air vessel consists of a special nickel steel forging containing highly compressed air which provides the motive power of the torpedo.

The balance chamber is a watertight compartment, which contains the depth-keeping mechanism and the heater apparatus and the supply of fuel (petroleum in a special flask). The depth-keeping mechanism consists of a pendulum weight so interlinked with a hydrostatic valve that the weight corrects departure from the horizontal, whilst the valve maintains the set depth, their joint action operating the horizontal rudders through the medium of a small air engine termed the servomotor.

The engine room is the next compartment abaft the balance chamber; it is watertight and together with the buoyancy chamber to which it is attached, forms what is known as the afterbody. This portion of the torpedo is secured to the balance chamber by a number of screwed bolts which allow of the torpedo being parted for examination of mechanism in the engine room. It consists of (a) the engines of the four cylinder single acting Brotherhood type; (b) the steering engine or servomotor; (c) the starting valve and counter gear; (d) the reducing valve which maintains an approximately constant working pressure at the engine irrespective of air vessel pressure; (e) oil bottles for lubricating working parts.

The starting valve is operated by an air lever which projects through the shell of the torpedo and is thrown aft on discharge by a downward projecting bolt in the torpedo tube. In addition to opening the starting valve, it releases the gyroscope. (f) The counter-gear, a piece of mechanism driven off the engines for stopping the torpedo at a definite range, or permitting it to run away. Off the counter is driven the ignition gear, whose function is to fire the cordite ignitres in the "heater," at a pre-determined moment and start the combustion of air and fuel. This gear can be set to float for practice or sunk for action; in the latter case a small valve is lifted at the end of the run admitting water to the buoyancy chamber, thus sinking the torpedo which might otherwise remain a floating mine.

The buoyancy chamber provides a large portion of the buoyancy of the torpedo. It consists of thin sheet steel, strengthened up internally to enable it to withstand external pressure, (a) impulse pressure on discharge, (b) immersion at great depth. The engines are secured to the foremost bulkhead of this compartment, and two watertight tubes run through it, one carrying the propeller shaft and the other carrying a rod connecting the servomotor and horizontal rudders. The sinking valve is on the bulkhead. The gyroscope is fixed to suitable brackets in this compartment, and connected to the vertical rudders. This piece of mechanism is a comparatively heavy bronze wheel mounted horizontally and vertically in gimbals. The gyroscope is released when the air lever is thrown aft, the wheel being initially spun to a high rate of revolution, due to the release of a strong spiral spring in torsion.

On discharge the whole system is freed from external constraint, and following the dynamical laws of rotating bodies the spinning axis tends to maintain its direction in space. It will be seen the axis of the spinning wheel provides a datum line, the direction of the gyro wheel on release. Subsequent deviations of the torpedo are corrected by the relative movements of the spinning axis and the fore and aft line of the torpedo. These relative movements control the air supply to a small steering engine which operates vertical rudders, so bringing the torpedo back to its original direction.

The tail carries the horizontal and vertical rudders which are mounted on corresponding fins; it also contains gearing to enable two four-bladed propellers to be driven in opposite directions off the engine and this ensures that the torpedo keeps its upright condition without heel, the turning effect of one propeller being balanced by the other. (See SUBMARINE WARFARE.) (W. M. M. R.)

**TOSTI, SIR FRANCESCO PAOLO** (1846–1916), Italian composer and teacher of singing, was born at Ortona, Abruzzi, April 9 1846. At the age of 14 he began his musical studies at Naples, where he studied under Mercadante and Carlo Conti. In the course of time he was appointed teacher of music to Queen Margherita, then a princess of Savoy and later became queen

of the musical archives of the Italian Court. In 1876 he paid his first visit to England; five years later he was appointed teacher of singing to the Royal family and settled in England. He published many songs, which from the first had a wide success, the most famous being "Goodbye," "Ask Me No More" and "For Ever." He was knighted in 1908 and died in Rome Dec. 2 1916.

**TOTEMISM:** see ANTHROPOLOGY.

**TOURNEUX, JEAN MAURICE** (1849–1916), French man of letters (see 27.107), died in Paris Jan. 13 1916.

**TOWN PLANNING:** see CITY PLANNING.

**TOWNSEND, MEREDITH WHITE** (1831–1911), British journalist was born at Bures, Suffolk, April 1 1831, and educated at Ipswich grammar school. In 1848 he went out to India, and four years later became editor of *The Friend of India*; acting also for some years as *The Times* London, correspondent. In 1860 he returned to England and in the following year purchased the weekly *Spectator* (see 19.562). With R. H. Hutton he was joint-editor until 1879, and he was largely instrumental in making it an established success, writing most of the political articles and the opening paragraphs every week. His two chief publications were *The Great Governing Families of England* (1865), written in conjunction with J. L. Sanford and *Asia and Europe* 4th ed. (1911). He died at Little Bookham, Surrey, Oct. 21 1911.

**TOY, CRAWFORD HOWELL** (1836–1919), American Hebrew scholar (see 27.114), died at Cambridge, Mass., May 12 1919. In 1913 he published *Introduction to the History of Religions*.

**TOZZI, FEDERIGO** (1883–1920), Italian novelist, was born at Siena Jan. 1 1883, the son of an innkeeper. His childhood and early youth are described in *Congli occhi chiusi* (1919). His father died in 1908, and Tozzi married the same year, and *Il Podere* (1921) is a record of his experiences at this time. He learnt Latin and studied old Tuscan, his first book being an *Antologia d'antichi scrittori senesi* (1913). But *Tre Croci* (1920) translated into English as *Three Crosses* (1921), the only one of his books which is not autobiographical, is considered his finest work. He died in Rome on March 21 1920, before he was able to reap the fame which the success of his latest work brought him. Tozzi, although all his work centres round his native place, Siena, does not speak with a provincial accent; his spirit is a universal spirit. He uses with success the curious power of presenting objectively a subtly psychological drama, and the nearest parallel to his methods is to be found in Chekhov.

**TRACKLAYING:** see RAILWAYS.

**TRACTORS.**—The petrol tractor for agricultural and kindred purposes is a development of the steam traction engine, widely used for operating grain threshers and to a small extent for ploughing. Steam ploughs were used toward the end of the 19th century on the large ranches of the northwestern section of the United States, in Canada and in Egypt. Their usefulness was limited, however, owing to their great weight, which resulted in the packing of the soil and in rather inefficient operation. When the weight of the petrol engine was greatly reduced by motor-car engineers, about 1900, the idea of substituting that type for the heavy steam plant naturally suggested itself.

## I. PRODUCTION AND MECHANISM

The first petrol tractors seem to have been those built by the Huber Mfg. Co., of Marion, Ohio, in 1898. These were not successful and only 30 were completed. In 1901 the Hart-Parr Mfg. Co., of Charles City, Iowa, engaged in the manufacture of petrol tractors, and, although it met with many difficulties, this company was successful. There are two general types of agricultural tractor, the wheeled and the crawler or caterpillar, types. The crawler type, in which the weight is spread over a large supporting surface on the ground, can pass over marshy land where the wheeled tractor would be mired, and when used for pulling harrows, seeders and other implements over ploughed ground, does not pack the soil as a wheeled tractor would. Early technical development was chiefly toward large tractors, designed to operate from 6 to 12 plough bottoms, because the only farmers who then took an interest in tractors owned large ranches in western America.

The largest producers of petrol tractors in the United States between 1905 and 1913 were manufacturers whose main line was general agricultural machinery and steam traction engines, such as the

International Harvester Co., the J. I. Case T. M. Co. and Emerson-Brantingham Company. The large petrol tractors of that period were crude in design and very heavy; their frames were built up of heavy rolled channels, and they had driving wheels of enormous diameter. Their great weight naturally rendered them inefficient, for a large proportion of the engine power was consumed in moving the tractor itself. The tractor shown in fig. 1 is characteristic of tractors of an earlier period.

FIG. 1.—Petrol Tractor of a type now obsolete.

**Agricultural Tractors.**—Tractors are usually rated in terms of the number of 14-in. plough bottoms they will pull. In 1925, of 104 models on the American market pulling two or more bottoms, 12 were two-plough tractors; 42 three-plough; 28 four-plough, and the rest were capable of pulling five or more ploughs up to a dozen. However, the tractors in the two-plough class were produced on the largest scale by far. Of a total of 134,590 tractors produced in the United States in 1923, 102,126 had a belt horse-power rating of 15–19, which corresponds to the two-plough class. Table I. shows the production of tractors in the United States from 1910 to 1923.

TABLE I. *Tractor Production in the United States*

|      |         |      |         |
|------|---------|------|---------|
| 1910 | 4,500   | 1919 | 136,162 |
| 1912 | 11,400  | 1920 | 203,300 |
| 1914 | 10,400  | 1921 | 73,198  |
| 1916 | 29,670  | 1922 | 99,692  |
| 1918 | 132,697 | 1923 | 134,590 |

According to statements of the Minister of Transport, between Jan. 1 and March 31 1921, there were registered in Great Britain 10,161 motor-ploughs and similar machines, for each of which an annual tax of 5s. was paid. For the same period in 1925 the figure was 14,079. According to the Ministry of Agriculture, from Jan. to Nov. 1921, there were registered in this class 18,100 machines, and from Jan. to Nov. 1924, 16,040. These figures, however, do not give an accurate idea of the number of agricultural tractors in service in Great Britain because the 5s. tax class includes other types of machines and, besides, as some of the tractors never use the public roads, their owners do not bother to register them. Of the tractors manufactured in the United States 14,854 (23.7%) were exported in 1917; 29,143 (14.3%) in 1920 and 16,643 (12.4%) in 1923. In 1912 the business in the large tractors of 6 to 12 plough capacities reached its zenith, and thereafter it declined rapidly.

The first popular small tractor, the Bull, was brought out the following year, and in 1914, no fewer than 3,000 tractors of this make were sold. Although smaller, it was still of the same crude design as the larger machines, with exposed gears, plain bearings and similar features. About 1916 a number of engineers with motor-car experience entered the tractor field, and as a result of their efforts tractor design was greatly improved. Many farm tractors were designed to use paraffin as fuel, because paraffin was considerably cheaper than petrol, and the conditions of engine operation on a tractor (constant speed and steady, heavy load) made it comparatively easy to burn paraffin with a moderate degree of success. Petrol, however, proved much more satisfactory in the average engine, and when in 1919 the price of paraffin advanced sharply, tractor users generally turned to

petrol. The consumption of petrol in gallons per acre is less, there is less difficulty in cold weather, and the oil in the crankcase does not lose its lubricating value so quickly.

**Typical Design.**—For the sake of economical manufacture many of the earlier small tractors were made with only three wheels, but the buying public did not approve of this feature of construction, and the typical 1925 wheeled tractor has four wheels, two in front for steering and two in the rear for driving. The Twin City 12–20 H.P. tractor shown in fig. 2 is a good example of the lighter tractors based on motor-car practice. The tractor industry was hard hit by the heavy slump in the prices of agricultural products which set in late in 1920. Prices of tractors and other agricultural machinery did not drop nearly

FIG. 2.—Twin City tractor, a light machine.

as rapidly nor as much as those of farm products, and the result was a "buyers' strike," the effect of which is clearly reflected in the production figures for 1921. When business came practically to a standstill, one manufacturer cut the price of his machine exactly in half (from \$790 to \$395). While losing money at the new price he hoped that the reduction would greatly increase the demand, and with increased demand and increased production the cost of manufacture would come down and profits return. A very keen price competition set in, and many tractor manufacturers went out of business during the next two years. The low level of prices reached in 1921 was not maintained, and in 1924, when the financial situation of the farming community improved, there was also a noticeable improvement in the tractor industry.

**The Fordson Tractor.**—A tractor which was manufactured in very large numbers and distributed all over the world was the Fordson, manufactured by the Ford Motor Co., Detroit, Michigan. A central longitudinal section of this machine is shown in fig. 3. It was of the frameless or backbone type, the crankcase

FIG. 3.—Fordson Tractor, showing longitudinal section.

of the engine and the cases of the change-speed gear and rear axle forming the supporting structure. The engine had four vertical cylinders of 4-in. bore and 5-in. stroke, which were cast in a single piece with the upper half of the crankcase, the lower half of this case being a separate casting. To the rear of the crankcase was bolted a housing which enclosed the flywheel, the friction clutch and the change gearing, and also formed the rear axle housing. There was no direct "through" drive, the power

being always transmitted from the upper to the lower of two parallel shafts in the gearset, and an extension of the lower shaft carried the worm which meshed with the worm wheel on the rear axle differential gear.

Changing of gear was effected not by meshing the gears, which remained in mesh continuously, but by securing one or another of the gears to the shaft by positive clutches. The rear wheels were 42 in. in diameter and the tractor was geared to give a ploughing speed of  $2\frac{1}{2}$  M.P.H. with an engine speed of 1,000 R.P.M. In addition to the ploughing speed there were provided a low forward speed and a reverse motion. Over the engine was mounted a double compartment fuel tank holding 1 gal. of petrol and 16 gal. of paraffin. Air was taken in through an air washer and the carburettor was of the Holley make in which the paraffin, after having been sprayed into a stream of air to form a very rich mixture, was vaporised by being passed between two stampings of sheet steel, the outer faces of which were in contact with the hot exhaust gases. Additional air was mixed with this rich mixture close to the inlet valves. Ignition was by a Ford fly-wheel magneto, engine lubrication by the circulating splash system, and circulation of the cooling water by the gravity or thermo-siphon system. Unlike most others, this tractor was not fitted with an engine governor by the maker, but several speciality manufacturers offered governors specially designed for it and many owners of the tractor fitted them. The Fordson tractor had a wheelbase of 63 in. and weighed 2,562 lb. complete. The front axle was swivelled at its centre on a saddle casting bolted to the front of the engine and was braced near its ends by radius rods with flexible joints extending to lugs cast on the bottom of the engine crankcase. A belt pulley for power work was provided and ran at engine speed.

**General Features.**—Belt pulleys formed a part of the equipment of practically all tractors, being used for operating threshing machines, wood saws, silo fillers, etc. It was customary to apply a double horsepower rating; for instance, a three-plough tractor was often rated as a 12-25 H.P. machine. This signified that the tractor could develop 25 H.P. on the belt and 12 H.P. on the drawbar, the difference of 13 H.P. being required for moving the tractor itself over the field. Four belt speeds were standardised, namely, 1,500, 2,600, 3,000 and 3,500 feet per minute.

The crawler tractor had one or two continuous-chain tracks on which it ran and which it carried with it. That portion of the chain track in contact with the ground had transverse projecting bars or depressions which caused it to grip the ground firmly, while the upper side of the lower portion of the chain formed a smooth track on which rolled idler wheels carried on the frame of the tractor. The power from the engine was transmitted through a suitable reduction gear to a pair of toothed wheels which engaged with teeth or rollers on the inner side of the track and, when power was applied by letting in the clutch, the tractor rolled ahead on the track and the track at the same time rolled forward. The power was applied to the two chain wheels through a differential gear, and in order to steer a tractor of this kind, one track was held stationary by a brake on the shaft of its chain wheel, while all the power was applied to the other chain wheel.

The Cletrack tractor shown (in fig. 4) was one of the smallest tractors of this type. Much of the development work in connection with crawler tractors was done in California, where the Holt, the Best and the Yuba, all tractors made in large sizes, originated. The Holt, which is called a caterpillar, became the prototype for the "tanks" (q.v.) which played such an important part in the World War. In 1925 many of these large crawler tractors were used for other than agricultural purposes—for example, in oil-fields, in lumbering and in road-building. The city of New York in 1920 purchased a large number for use in clearing the streets of snow. The lumbering or logging work done was mainly in swampy districts where horses cannot work except in winter when the ground is frozen, whereas the crawler tractors make logging in such districts possible the year round. The weight on the track of a crawler tractor of the 1925 type was as low as 5 lb. per sq. in., and such a tractor could go into boggy places where no wheeled vehicles could follow.

**Nebraska Legislation.**—In 1919 the Legislature of the State of Nebraska passed a law providing that thereafter no tractor should be sold in that state until the manufacturer had first

FIG. 4. Cletrack tractor, a small machine.

submitted a sample tractor for trial to the agricultural Engineering Dept. of the University of Nebraska and the tractor had satisfactorily met the test required. The manufacturer must also satisfy the state authorities that he is maintaining an adequate supply of repair parts within the state. This legislation was the result of complaints of farmers that manufacturers were over-rating their tractors. The result was that, during a period when 66 tractors were tested, the makers of 8 were compelled to increase their rated engine speed, 13 lowered their horsepower rating, 14 changed some part and 4 withdrew. Up to 1925 no other states had passed similar laws, but the Nebraska test results were widely published and served for the whole country.

## II. COST AND USES

The three chief items of cost in tractor ploughing are fuel, depreciation and labour. At the tractor trials held at Lincoln, England, in the autumn of 1919, the fuel consumption per ac. averaged almost exactly 4 imp. gal. for ploughing in heavy clay soil, and 3 gal. for ploughing on cliff lands. In the corn belt of the United States, where the soil is comparatively light, it has been customary to reckon on a fuel consumption (either petrol or paraffin) of 2.5 U.S. gal. (2 imp. gal.) per acre. On the other hand, in a *Bulletin* of the U.S. Dept. of Agriculture on "The Gas Tractor in Eastern Farming," a fuel consumption of  $3\frac{1}{2}$  U.S. gal. per ac. is made the basis of cost calculations of the eastern section, and in the tractor trials held at Harrisburg, Pa., in 1919, the average fuel consumption of all tractors using paraffin worked out at 3.28 U.S. gal. (2.62 imp. gal.) per acre. The fuel consumption in tractor ploughing varies both with the character and condition of the soil and with the depth of ploughing. The average depth of ploughing at Lincoln was 5 $\frac{1}{2}$  inches. The resistance of the soil (drawbar pull) averaged 11.5 lb. per sq. in. for the heavy clay soil and 9 lb. per sq. in. for the cliff land. In the corn belt of the United States the soil resistance generally varies between 5.5 and 7 lb. per sq. in., and this explains the low fuel consumption in ploughing there. The estimate here given of the cost of ploughing one acre is based on the results of an inquiry by the U.S. Dept. of Agriculture among 400 tractor farmers in the Dakotas concerning their experiences in 1917 and 1918. Only one change is made from the estimate of the department, namely, the assumption of a tractor life of seven instead of nine years. The answers to the questionnaire yielded the averages shown in Table II.

TABLE II. Average Cost and Performance of Tractor Ploughing in the Dakotas.

|                                  | Two-plough<br>Tractors | Three-<br>plough<br>Tractors | Four-<br>plough<br>Tractors |
|----------------------------------|------------------------|------------------------------|-----------------------------|
| First cost                       | \$1,050                | \$1,460                      | \$2,000                     |
| Full working days per<br>year    | 45                     | 52                           | 64                          |
| Acres ploughed per<br>10-hr. day | 6.3                    | 8.5                          | 10.9                        |

FIG. 1. Silo being filled by power from tractor. FIG. 2. Two-ton caterpillar tractor pulling 3" tandem disc and harrow. FIG. 3. Fordson tractor as used for pushing copper bars. FIG. 4. 10-inch flexible creeper (Kegresse system of propulsion) on 2-ton Delahaye truck. This type of creeper-band has been successfully used in crossing the great Sahara desert by motor. (Photo Meurisse). FIG. 5. Mack semi-tractor, capacity 26,000 lb., pulling a tank-car semi-trailer.

Other factors on which the estimate is based are the following: cost of petrol, \$.276 per U.S. gal.; paraffin, \$.152 per gal.; lubricating oil, \$.50 per gal.; grease \$.10 per lb.; repairs, 4% of the first cost per year; depreciation on a 7-year basis; man labour at \$4.00 per day; interest at 6% on the average investment (one-half of total investment). Such items as housing, insurance and taxes are neglected.

TABLE III. *Cost of Tractor Ploughing in the Dakotas 1917-8*  
(Dollars per acre)

| Size of Tractor | Total Cost of Ploughing |                  | Fuel   |          | Oil   |
|-----------------|-------------------------|------------------|--------|----------|-------|
|                 | Petrol Tractor          | Paraffin Tractor | Petrol | Paraffin |       |
| Two-plough      | 2.21                    | 1.915            | 0.69   | 0.395    | 0.075 |
| Three-plough    | 1.975                   | 1.68             | 0.69   | 0.395    | 0.075 |
| Four-plough     | 1.757                   | 1.462            | 0.69   | 0.395    | 0.075 |

#### Other Items

|              | Grease | Repairs | Depreciation | Man Labour | Interest |
|--------------|--------|---------|--------------|------------|----------|
| Two-plough   | 0.02   | 0.15    | 0.53         | 0.635      | 0.11     |
| Three-plough | 0.02   | 0.13    | 0.49         | 0.47       | 0.10     |
| Four-plough  | 0.02   | 0.11    | 0.409        | 0.368      | 0.085    |

With these data a close estimate can be made of the cost of tractor ploughing under different conditions, as all the basic costs are given. The average soil resistance in the Dakotas may be assumed to be 8 lb. per sq. inch. In heavier soils the area ploughed per day will be less in substantially the inverse ratio of the soil resistance (provided the latter is not excessive). This is borne out by estimates of the ploughing capacities of the tractors which competed in the Lincoln trials of 1919, made by the judges of the event. Averaging the estimates for heavy clay soil (soil resistance 11.5 lb. per sq. in.), and reckoning on the basis of a 10-hr. instead of an 8-hr. day, the following results are obtained: Two-plough tractor,  $4\frac{1}{2}$  ac., three-plough tractor,  $5\frac{1}{2}$  ac., four-plough tractor,  $6\frac{1}{2}$  acres.

As the application of tractors increased in the United States the average number of full days use per year decreased, which is partly accounted for by the fact that the large farms had the tractor first, and the smaller ones, which put it in service in later years, had not so much work for it. An inquiry made by the U.S. Dept. of Agriculture in 1922 showed that in the Corn Belt in the Middle West the average full days use of the tractor was 31.

**Power Take-off.**—One of the developments in tractor work that came shortly before 1925 was the provision of a power take-off by means of which power can be transmitted from the tractor to the implement drawn by it, for operating the mechanism of the implement, as, for instance, the sickle and binding mechanism of a grain binder, for which a small separate engine was sometimes used previously. According to an American agricultural standard, power take-offs are designed to turn at 536 (plus or minus 20) R.P.M. and in a clockwise direction when viewed in the direction in which the tractor travels.

**Advantages.**—To the American and Canadian farmer the advantage of the tractor is not so much that it reduces the cost of ploughing as compared with horses, as that it enables one man to work a much greater acreage. Approximately one-third of several hundred tractor farmers in Illinois circularised by the U.S. Dept. of Agriculture had increased their acreage by purchasing tractors. Another great advantage is that the tractor permits work to be done quickly when the weather is favourable. Power farming has proved particularly advantageous in the wheat belt of Kansas. For the best yield the land must be ploughed in August, when the temperature is often above 100° F. in the shade and very little work can be accomplished with horses. The tractor works as efficiently at this temperature as in winter. Moreover, the tractor can be used also for threshing, and the old practice of contract threshing has been largely superseded by the plan of four or five farmers owning a small threshing machine co-operatively and helping each other thresh their grain, each using his own tractor as the motive power. A three-plough tractor is generally recommended for a 20×36 in. grain separator. Sometimes it is necessary to get a crop into the ground very quickly, and, with a double shift of operators, tractors can then be operated continuously day and night.

**Development in Europe.**—Interest in farm tractors increased greatly in Europe during and following the World War. In 1919 and 1920 tractor trials were held at Lincoln, England, the first under the auspices of the Society of Motor Manufacturers and Traders and the second under that of the Royal Agricultural Society. The French Govt. in 1920 paid a bonus of 25% on the purchase price of tractors of domestic manufacture and 10% on tractors of foreign manufacture. French engineers paid particular attention to tractors for use in vineyards, which must be very narrow. Tractor development and application in Europe also received a severe setback about the time of the world-wide business depression of 1921, chiefly owing to the high cost of the fuel. The tractor trials of the Royal Agricultural Society were not repeated after that date, and in France the high cost of petroleum fuel was said to make tractor ploughing impracticable economically. Attempts were made to solve the fuel problem by the development of portable suction gas plants, but in 1925 tractors so equipped were not yet in regular production.

**Use in Orchards, etc.**—Tractors for use in orchards, on which a number of American makers specialise, must be of lower build than those for general use. A distinct type is the garden tractor, for the cultivation of row crops and general work in market gardening. The Beeman, the first tractor of this type, was put on the market in 1915, and in 1923 the total number of such tractors produced in the United States (by nine manufacturers) was 2,682 (see MOTOR VEHICLES).

**TRACY, BENJAMIN FRANKLIN** (1830-1915), American soldier (see 27.127), died in New York City Aug. 6 1915.

**TRADE** (see 3.235).—Trade is the business of buying and selling commodities. By a natural transition of thought and usage the term is applied also to the goods themselves. The expression "international trade" is likewise employed to refer both to the business or occupation of buying goods in a foreign country and of selling them abroad and to the goods themselves. In practice, however, the term country or "nation" in this connection is used to mean not necessarily a separate political entity, but a territory with an independent customs frontier, when such frontier exists. Thus, since the customs convention of May 1 1922, between Belgium and Luxembourg, it is no longer possible to speak of international trade between these two political entities.

#### THE COMPARABILITY OF FOREIGN TRADE STATISTICS

In most countries careful records are kept of the quantity and value of goods crossing the customs frontier and great importance is attached to the expansion or contraction of the quantum of trade, although there is no necessary connection between the growth of a country's trade and its general economic prosperity. But neither the quantum nor the value of that trade can be measured with any nice degree of accuracy. The difficulties which present themselves are due in part to the different systems of measurement adopted in different countries, in part to the recent alterations which have been introduced in those systems, in part to changes in the composition of world trade, and in part to changes in value.

**Two Main Divisions.**—Although the trade statistics of no two lands are compiled on exactly similar principles, it is customary and on the whole the custom is justified, to divide the world into two broad divisions of countries consisting of those which enforce the "continental" and those which enforce the "Anglo-Saxon" system. The former show what is called general and special trade, "general trade" meaning all imports into warehouse and exports therefrom, and "special trade" all "imports for domestic consumption" and all exports of "national and nationalised produce." The latter publish

"imports" and "exports," which are roughly equivalent to the general trade of the first division of countries, transshipment, transit and temporary trade and re-exports of foreign produce normally being excluded.

Were the definition of nationalisation of foreign goods uniform in all countries the existence of these two different systems would be of no great importance, because the imports, less the re-exports, of the "Anglo-Saxon" countries would be roughly equivalent to the special imports of the "continental" group, and the exports of the one and the special exports of the other would likewise be approximately comparable. But in the great majority of countries adopting the continental system all goods which have entered the free domestic market are considered as being for domestic consumption and all goods exported from the free domestic market as being national or nationalised. When an import duty is imposed on goods entering the domestic markets this supposition is generally justified; but in the case of raw materials, which are usually free of duty, it may frequently be quite unfounded. As a result the special imports and exports of countries adopting the continental system tend to include a certain amount of commerce which would be excluded from the statistics (imports minus re-exports and exports) of countries employing the Anglo-Saxon system.

The second great difference of method lies in the systems of valuation. In certain countries the goods are valued at average prices fixed by a government commission. These prices may or may not be differentiated by countries or be applied equally to imports and exports. Normally they are revised once a year, with the result that the trade of any given year is valued at prices ruling during the previous twelve months. In others and now in the majority of countries, the values recorded in the trade statistics are based on the declarations of the importers and exporters, which are checked against the documents accompanying the goods. Were the official valuations accurate and the merchants' declarations always honest, the coexistence of these two systems would be of little importance. But in post-war years the violent fluctuations of prices rendered the official valuations useless and the great majority of countries abandoned them in favour of merchants' declarations. This change, while increasing the comparability of trade statistics in the last year or two has rendered the annual national statistics of certain countries incomparable at various dates since 1917. Moreover, the "declared value" system demands a degree of commercial honesty and administrative competence to which all communities cannot lay claim.

A further difficulty arises on account of the fact that certain imports and exports are not included in all statistics—the commonest exclusions being gold and bullion, goods sent by parcel post, government stores, ships and ships' stores. The importance of such exclusions may vary enormously from one year to another. Thus, the British trade statistics during the War up to July 1917 were rendered quite misleading by the exclusion of all articles, other than food, imported on British Govt. account.

*Difficulties of Measuring Values.*—These three difficulties all relate to the manner in which national trade statistics are compiled. But even were all countries to adopt a common system, it would still be impossible to measure accurately the volume or value of world trade during the years immediately succeeding the War; still less during the war period. In order to measure changes in volume either the goods must be so similar in kind that they can be measured in some common unit of weight or they must be reduced to some other common denominator. But the only available common denominator—price—has undergone such violent changes in recent years as to render the trade statistics of many countries almost meaningless. At the same time, and largely as a result of relative price changes, the composition of international trade has been greatly modified. In each country an unequivocal trade price index may be compiled by taking fixed commodity weights equivalent to the importance of each class of goods on a given date. Such a procedure postulates that the relative importance of each commodity has remained unchanged.

The quantitative importance of the various commodities of

which the trade of any country is composed has, however, in most cases changed very considerably since 1914 and even in 1924 when world economic conditions had become more normal the catena of commodities arranged in the order of their "full value" importance was by no means identical with that of 1913. As a result indices so compiled, though unequivocal in the sense that their oscillations are dependent on changes in values only, are based on a hypothesis which we know to be untrue. In addition to this difficulty the indices are liable to be misleading because the apparent changes in values may be due, not simply to an alteration of price, but to a modification of the quality of the article the price of which is measured. In other words the second necessary hypothesis, that the character of the goods measured remains unaltered, may likewise prove untrue. Such indices have, however, been compiled in a number of countries based, as a rule, on a pre-war "weighting" and attempts have been made to show the variations in the quantum of trade by dividing the values of imports and exports by them. The results, for the reasons just given, cannot be accepted as giving more than a rough indication of the general character and trend of the changes which have taken place.

The international problem presents similar, though even greater, difficulties than the national. First it is necessary to convert the national currencies into some common unit of measure, a conversion which during periods of very rapid inflation involves great risk of error. Secondly it is necessary to compile a price index of all goods entering into international trade from the various national trade value indices. This composite index must be weighted according to the relative importance of the trade of each country in some given year, preferably the base year of the national indices. But just as it is not true that the relative importance of different goods entering into the trade of any single country has remained unchanged, so also is it not true that the relative importance to world trade of the imports or exports of each country is the same now as it was in 1913. Different results will be obtained if the standard year adopted be, for instance, 1913 or 1924. An analysis of the data for these two years, however, will show that the differences are not very great.

In a publication of the League of Nations entitled *Memorandum on Balance of Payments and Foreign Trade Balances* (1925) an attempt is made to obtain a rough measure of the changes which have taken place since 1913 in the general level of the prices of the goods composing world trade in 1924 by means of these trade value indices. The conclusion reached is "that it is not unreasonable to presume that the average gold value of the goods entering into international trade in 1923 was somewhere between 40% and 50% higher than in 1913 and that in 1924 it was nearer the latter than the former figure." During the years immediately preceding 1924 the difficulties of international comparison were so grave, and the reliability of national statistics so questionable, that no attempt to estimate the volume of world trade could be justified. By 1924, however, prices throughout the world had become so far stabilised, and the movements of the exchanges so far reduced as to render reasonable the belief that the published estimates of world trade present at any rate data from which certain very general conclusions may be drawn.

#### CHANGES IN THE VOLUME OF WORLD TRADE

If the calculations made by the League of Nations be accepted as a rough guide, and the results obtained are in accordance with the general evidence available from other sources, then it would seem probable that the total quantum of world trade in 1913 and in 1924 did not differ greatly. Possibly in the later year it was still slightly less than in the earlier.

In the accompanying table the imports and exports and total trade in terms of dollars of the very great majority (136 in 1924) of the independent trade statistical areas are given for the years 1913 and 1924.

The table is not quite complete, as statistics for a few countries, none of any great importance, are not available. It is further not absolutely accurate. In certain cases the figures for 1924 have not been published and those for 1923, occasionally even 1922, have had

Trade of 1913 and 1924 Reduced to Dollars (000,000's Omitted), Merchandise Only  
(Figures in brackets are for the latest available previous year)

| Country                            | Imports       |        |               |        | Exports       |        |               |        | Total         |        |               |        |

<sup>1</sup> Changes in territory.

<sup>2</sup> Includes bullion and, in some cases, small amounts of specie.

<sup>3</sup> The figures for Iraq, Syria and Palestine are included under Turkey.

to be interpolated; in others it proved impossible to exclude specie and gold bullion; in others general trade had to be given instead of special. In addition the statistics are subject to all the reservations and qualifications to which reference has already been made. All countries the total trade of which in 1924 was less than \$75,000,000 have been grouped together. The Netherlands have been omitted altogether, because the system employed in the compilations of their trade statistics was so radically changed in 1917 as to render the returns before and after that year quite incomparable. The Russian statistics for 1924 have been increased by 50%, i.e., by what would appear to be the approximate average rise in the value of goods constituting world trade, as the published figures are based on the average prices ruling in 1913. Certain other minor adjustments of the published data have also been made.

The total imports in 1924 of all the countries shown in the table are 145% of the imports in 1913 and the total exports 148% of the pre-war 1913 figure. These percentages are remarkably close to the probable change in value of goods and in so far as the figures constitute reliable evidence concerning the actual facts, would point to the conclusion mentioned above, that any difference which there may have been in the total quantum of world trade in the two years considered cannot have been very great. In this connection attention must again be drawn to the fact that the countries of which the world is composed are no longer the same as before the War. What has been the effect on the trade of France of the accession of Alsace or on the trade of Belgium of the Zollverein with Luxembourg it is impossible to estimate. Some of the international trade of the Austro-Hungarian Succession States to-day was domestic trade

before the War: some pre-War foreign trade, as for instance that between Transylvania and the old Kingdom of Rumania, has now become domestic. The Balfour Committee on Industry and Trade estimates that the existence of the Irish Free State resulted in an apparent inflation of the quantum of British exports in 1924 by 6%, and it is probable that on balance the result of the new territorial divisions has been to raise the foreign trade statistics by the inclusion of a net amount of exports and imports which in 1913 would have been domestic trade.

#### THE DISTRIBUTION OF INTERNATIONAL TRADE

Although the total quantum of world trade in 1924 was probably not much less than before the War, the share which the various countries of the world could claim therein was widely different. The first place in the list of exporting countries had been surrendered by the United Kingdom to the United States. The exports of Canada, Japan, China, Cuba, the Dutch East Indies, Mexico, New Zealand, Hawaii, Colombia, all more than doubled during the period. The German percentage fell from 13.1 to 5.7; that of Belgium from 3.8 to 2.4; that of Russia, after raising the Russian values which are expressed in terms of pre-War prices by the approximate average rise in gold prices, namely 50%, from about 4.2% to about 0.9%. The share of the United Kingdom was likewise slightly reduced from 13.97 to 12.96%, or if the necessary adjustments be made on account of trade with the Irish Free State probably to about 12.2%. On the other hand, India and the British dominions, with the exception of South Africa, gained ground. The percentages of the more important trading divisions of the British Empire may with advantage be grouped together.

*Percentages of World Totals*

|                               | Imports |       | Exports |       | Total Trade |       |
|-------------------------------|---------|-------|---------|-------|-------------|-------|
|                               | 1913    | 1924  | 1913    | 1924  | 1913        | 1924  |
| United Kingdom . . . .        | 16.49   | 17.89 | 13.97   | 12.96 | 15.27       | 15.47 |
| India . . . . .               | 3.01    | 2.67  | 4.22    | 4.35  | 3.60        | 3.49  |
| Canada . . . . .              | 3.18    | 2.80  | 2.36    | 3.94  | 2.78        | 3.36  |
| Australia . . . . .           | 1.95    | 2.28  | 2.05    | 2.32  | 2.00        | 2.30  |
| Straits Settlements . . .     | 1.32    | 1.55  | 1.16    | 1.45  | 1.24        | 1.50  |
| Union of South Africa . . . . | 1.03    | 1.03  | 1.73    | 1.37  | 1.37        | 1.20  |
| New Zealand . . . . .         | 0.52    | 0.76  | 0.56    | 0.84  | 0.54        | 0.80  |
| Ceylon . . . . .              | 0.31    | 0.35  | 0.41    | 0.45  | 0.36        | 0.40  |
| Federated Malay States . .    | 0.23    | 0.18  | 0.41    | 0.41  | 0.32        | 0.29  |
| Total . . . . .               | 28.03   | 29.51 | 26.87   | 28.09 | 27.48       | 28.81 |

Thus the total share of the British Empire, exclusive of the smaller Crown colonies, etc., slightly increased. The British percentages are based on the published official figures without adjustments on account of Irish trade. Their contraction and the considerable augmentation of Canadian and New Zealand trade is typical of world movements and the shift of the centre of gravity towards America and the economically younger countries of the world.

The change in the contribution of different quarters of the globe to the totality of world trade may be conveniently summarised by showing the percentage distribution of world trade by continental groups.

*Percentage Distribution of World Trade*

|                                                 | Imports |       | Exports |       | Total |       |
|-------------------------------------------------|---------|-------|---------|-------|-------|-------|
|                                                 | 1913    | 1924  | 1913    | 1924  | 1913  | 1924  |
| 1. Central and Eastern Europe (included in [2]) | 21.28   | 14.52 | 21.57   | 12.16 | 21.43 | 13.35 |
| 2. Europe . . . . .                             | 61.69   | 55.73 | 55.39   | 45.17 | 58.64 | 50.55 |
| 3. North America . . .                          | 12.20   | 15.31 | 15.56   | 20.31 | 13.81 | 17.76 |
| 4. Caribbean . . . . .                          | 2.06    | 2.58  | 2.68    | 3.91  | 2.36  | 3.23  |
| 5. South America . . .                          | 5.64    | 4.68  | 6.67    | 6.57  | 6.14  | 5.62  |
| 6. Africa . . . . .                             | 3.94    | 3.78  | 4.05    | 4.26  | 4.18  | 4.02  |
| 7. Asia . . . . .                               | 11.96   | 14.84 | 12.63   | 16.58 | 12.29 | 15.68 |
| 8. Oceania . . . . .                            | 2.51    | 3.08  | 2.66    | 3.20  | 2.58  | 3.14  |
| Total 2-8 . . . . .                             | 100     | 100   | 100     | 100   | 100   | 100   |

The division of the states or trade statistical areas into the groups given is necessarily more or less arbitrary and opinion may well differ concerning the group into which this or that island should be placed. The first division is supplementary to the others and consists of Austria, Bulgaria, Czechoslovakia, Estonia, Germany, Hungary, Latvia, Lithuania, Poland, Rumania, Russia and the Kingdom of the Serbs, Croats and Slovenes in 1924 and of Austria-Hungary, Bulgaria, Germany, Rumania, Russia and Serbia in 1913. Its share in world trade in 1924 had shrunk to about 62% of what it was before the War, despite the increase in the number of trading units.

The European contraction is largely due to the great diminution in the international exchange of goods in the eastern and central countries; but the rest of Europe had not quite recovered its position in this year. There has been a definite shift from the Atlantic Ocean to the Pacific and that group of countries, the United States of America, Canada, Japan, China (in 1924) New Zealand and Australia, whose prosperity accounted in so great a degree for the elevation of the total volume of trade in 1924 towards the pre-War level, have tended to trade more with each other. This tendency may be illustrated by showing the distribution of the trade of certain of these countries by continental groups.

*Exports—Percentage Distribution*

| From:     | To:  | Europe | N. America | Caribbean | S. America | Africa | Asia | Oceania |
|-----------|------|--------|------------|-----------|------------|--------|------|---------|
| U.S.A.    | 1913 | 60.4   | 16.5       | 7.7       | 5.9        | 1.1    | 5.1  | 3.3     |
|           | 1924 | 53.3   | 13.9       | 9.9       | 6.9        | 1.5    | 11.2 | 3.4     |
| India     | 1913 | 57.9   | 9.5        | 0.4       | 2.0        | 2.8    | 25.3 | 2.0     |
|           | 1924 | 50.9   | 9.5        | 1.3       | 2.2        | 5.8    | 28.2 | 2.1     |
| Canada    | 1913 | 54.7   | 39.0       | 1.8       | 0.9        | 1.0    | 1.1  | 1.5     |
|           | 1924 | 47.9   | 40.5       | 2.3       | 1.9        | 1.1    | 3.7  | 2.6     |
| China     | 1913 | 25.2   | 9.2        | 0.0       | 0.0        | 0.0    | 65.4 | 0.1     |
|           | 1924 | 18.0   | 13.4       | 0.0       | 0.1        | 0.0    | 68.4 | 0.1     |
| Australia | 1913 | 77.6   | 3.6        | 0.0       | 1.1        | 3.7    | 9.3  | 4.7     |
|           | 1924 | 66.0   | 6.2        | 0.0       | 0.1        | 3.8    | 18.2 | 5.7     |

If the imports be analysed in the same way, or the distribution by countries instead of by continental groups be taken, confirmatory evidence of this shift of trade towards the Pacific Ocean will be obtained.

There is no doubt, however, that European exports were appreciably greater in 1924 than in 1923 or 1922 and since 1918 a marked change has taken place in the balance of exports and imports. This change is illustrated for certain countries below:—

*Exports as a Percentage of Imports*

|                        | 1913  | 1919  | 1924  |
|------------------------|-------|-------|-------|
| Belgium . . . . .      | 73.6  | 43.9  | 79.2  |
| Czechoslovakia . . . . | ..    | 81.2  | 107.2 |
| Denmark . . . . .      | 81.9  | 30.4  | 90.4  |
| Finland . . . . .      | 81.3  | 35.1  | 105.4 |
| France . . . . .       | 77.8  | 33.1  | 103.6 |
| Germany . . . . .      | 91.0  | 31.1  | 70.5  |
| Italy . . . . .        | 70.7  | 36.5  | 73.8  |
| Netherlands . . . . .  | 78.7  | 52.5  | 75.8  |
| Norway . . . . .       | 69.6  | 28.8  | 68.3  |
| Rumania . . . . .      | 112.7 | 2.8   | 105.8 |
| Russia . . . . .       | 110.6 | 0.01  | 116.0 |
| Sweden . . . . .       | 95.2  | 61.3  | 92.3  |
| Switzerland . . . . .  | 71.3  | 92.1  | 85.1  |
| United Kingdom . . . . | 80.1  | 54.6  | 72.1  |
| Argentina . . . . .    | 103.6 | 149.8 | 124.7 |
| Australia . . . . .    | 98.5  | 111.7 | 84.6  |
| New Zealand . . . . .  | 103.2 | 179.5 | 108.5 |
| South Africa . . . . . | 155.8 | 200.2 | 118.7 |
| Canada . . . . .       | 71.8  | 116.3 | 135.7 |
| U.S.A. . . . .         | 138.8 | 209.3 | 117.5 |

The gap between the total of exports and imports may be covered in a number of different ways (see BALANCE OF

PAYMENTS); but in the majority of cases the most important factors are capital borrowings, loans, interest on loans and freight. In 1919 Europe was living to a large extent upon money borrowed in the United States of America and upon short term credits advanced by countries producing raw materials. By 1924 much more normal conditions had been restored. The younger countries of the world showed a slight excess of exports on account, not of credits they were advancing, but of interest payments on old loans; and Europe showed a balance of imports and exports not greatly dissimilar from the pre-war balance.

For a number of countries it is possible to obtain an approximate idea of the changes which have taken place in the quantum of their commerce by dividing the statistics of trade by value by the trade price indices discussed above. The results are necessarily not exact, but in most cases they probably give a correct indication of the direction of recent movements.

|                |              | 1913 | 1919 | 1920 | 1921 | 1922 | 1923            | 1924             |
|----------------|--------------|------|------|------|------|------|-----------------|------------------|

<sup>1</sup> Approximate adjustments for the Irish Free State would give:—

|      | Imports | Exports | Re-exports | Total Exports |
|------|---------|---------|------------|---------------|
| 1923 | 93      | 75      | 81         | 76            |
| 1924 | 104     | 76      | 90         | 78            |

*A British Enquiry.*—The (Balfour) Committee on Industry and Trade draws attention to the possibility that the British indices of the quantum of trade "give somewhat too dark a picture of the recent and present trade position. . . . There is ground for belief that some part of this wide divergence is due to a shift of export trade towards the higher and more expensive qualities of goods, which could not be fully taken into account in the calculation. . . . Exactly how much of the apparent rise is referable to this cause is difficult to estimate, but the available indications would seem to support the view that the true rise of the level of export prices has not exceeded 80%. If the consequential modifications were made in the figures given above, we should find that the volume of our exports in 1923 was 79% of the 1913 volume and that the corresponding figure for 1924 was 80%. Meanwhile the volume of our imports in the same two years was 94.9% and 106.4% respectively of the 1913 volume."<sup>1</sup>

<sup>1</sup> The word "volume" in the quotation is used in the same sense as "quantum" elsewhere in this article, *i.e.*, to mean value corrected for changes in price.

These revised percentages refer to the figures given in the footnote to the table above adjusted for the change in the status of the Irish Free State. The reduction in the British quantum export index is in part offset by an increase in the average price of the exports greater than the rise in world prices. The same fact is true of Sweden and Switzerland and countries which like the United Kingdom slowly brought their currencies back to par with the dollar by a painful process of protracted deflation.

Although the recovery from the after-effects of the War was not complete, great progress has been made since the slump of 1921. Thus the quantum of exports, (*i.e.*, the recorded values divided by the trade-price index) of Denmark increased between 1922 and 1924 by 38%, of Finland by 20%, of Norway by 12%, of Sweden by 13%. With the rise in prices in Germany towards the world level during the last stages of inflation and after the stabilisation of her prices, there was a contraction in the quantum of her trade, a contraction, however, which was more than counter-balanced by the higher prices at which she sold her wares. For France there is no quantum index, but her trade has grown steadily and is now greater than before the War.

The picture which the present state of world trade presents is similar to that which would be obtained from an array of the facts relating to the production of raw materials, or cereals or any other indicators of national prosperity. Europe and European production has been affected to some extent by agrarian reform, by tariffs and prohibitions, by the social revolution in Russia. But the main cause of the change in the balance of importance of the great continental groups into which the world is divided is that whereas elsewhere the normal progress of a decade has been achieved, Europe has still not recovered from the War and all the economic ills to which the War gave birth.

(A. Ly.)

**TRADE BOARDS.**—In Great Britain a trade board is a statutory body set up by the Board of Trade or since 1918 by the Ministry of Labour for the purpose of fixing minimum rates of wages in the industry for which it is established. Under the Trade Boards Act of 1909 trade boards were set up in eight trades, but the scope of this Act was greatly widened by an amending Act of 1918 with the result that at the end of 1920 additional trade boards had been set up in 49 trades covering about 3,500,000 persons. The Act of 1909 resulted from a long and sustained agitation, following the revelations as to the earnings and general working conditions of "sweated" workers, which were made in the late years of the last century and the first years of the present. The public conscience was stirred and action was motivated by the humane desire to afford some protection to those suffering under the "sweating" system. While the prime motive was humane, the sociological and economic arguments for the protection demanded were not, of course, overlooked.

*Regulation of Wages.*—The humane case for the prevention of sweating does not need elaboration. The sociological and economic arguments are interdependent and are based on the view that any industry must, if it is to maintain an economically sound position, pay to the workers engaged in it wages sufficient for the maintenance of those workers and their families. Failure to do so means that the industry concerned is subsidised by Society ("Society" including other industries), in so far as the workers employed in it ultimately become a charge on the State. The charge may be direct, by way of more than normal calls on the public health services, free school meals, or, often enough, through the Poor Law itself, or it may be indirect, taking the subtle form of the mental, physical and spiritual degradation of the workers and citizens who are "sweated."

The decision to legislate against "sweating" is, however, only the beginning of the problem, and several important questions as

to the means to be adopted remain to be settled. Is there to be one minimum for all the trades concerned or a separate minimum for each trade? If separate minima are to be fixed, what bodies shall be the fixing authorities? Is the minimum to be a guaranteed income or only a guaranteed rate of wages? On what basis shall the minimum be fixed? What shall be the relation between men's and women's wages? Shall district variations in the cost of living or the nature of the work be taken into account in fixing the minima?

The multiplicity and diversity of these questions led to the conclusion that it was impossible to fix one minimum to apply equally to all "sweated" trades and, this being recognised, it was clear that each minimum might best be fixed by a body constituted of persons drawn from the trade itself. Thus trade boards were established consisting of equal numbers of employers' and workers' representatives, together with a small quota of neutral persons in order that a deadlock might be avoided. It was equally clear that the question of a guaranteed income could not be considered in relation to a comparatively small and ill-conditioned group of trades only, and hence the boards were empowered to fix, not guaranteed wages, but minimum rates of wages.

On whatever basis the trade boards may choose to fix their rates—and on this point the Acts give no specific guidance—the rates fixed are to be regarded strictly as *minimum* rates, to pay below which is an injustice to be remedied by the criminal law. Thus there is nothing of the system of compulsory arbitration in trade boards. Any worker, or his trade union on his behalf, is free to get as much more than the trade board rate as he can. But an employer may not pay less.

The remaining questions were referred to the boards for settlement, and thus have been dealt with in accordance with the customs and circumstances of each trade. There can be no doubt that this was the wisest course and the one likely to cause least disturbance and friction in the trades concerned.

It has been noted that the Acts give no specific guidance to the boards as to the basis on which rates of wages shall be fixed. In some other countries in which minimum wage legislation is effective, principles for the fixing of such wages have been laid down more or less precisely by the legislature or have been formulated in the course of practice, but in Great Britain the boards have only the known intention of the Acts to guide them. Parliament, however, retains some control over rates fixed through the Minister of Labour, by whom all rates must be confirmed before they become operative. It is an important point, however, that the Minister's power is restricted to the confirmation or reference back to the board of rates submitted to him. He may not alter any rate submitted to him, nor may he fix a rate, and thus, subject only to the veto of the Minister, the power to determine precisely what rate shall operate lies solely with the Trade Board.

As might be expected, the workers' representatives on the boards lay stress on the "living wage" argument in the proceedings of the boards. Employers' representatives pay chief regard to "what the trade can bear." It is the task of the independent members, with the intention of the Acts in mind, to bring about some compromise acceptable to both sides, or in the last resort to vote with one side against the other. As a result of this procedure the rate which is fixed may not produce in the full sense of the term a "living wage." Particularly is this the case in the early stages of a Trade Board, when the immediate fixing of a rate which would adequately fulfil the purpose of the Acts might cause disturbance of employment. In such cases, the final rate may be reached in two or more stages. In this way the trade board system enables the circumstances of each separate trade to be considered when the rate is fixed. Each trade moreover, is able to vary its own minimum rates at any time without waiting upon the remaining trades. Again, the flexibility of the trade board system permits of the adjustment, in accordance with the prevailing customs of each trade, of the relation between men's and women's wages. While, owing to varying customs, there are some exceptions, in

general the rates fixed for women will be found to be round about 60% of those fixed for men, which is in accord with the prevailing custom of industry as a whole. A few, but only a few, of the boards have taken into account variations in the cost of living in different districts and have accordingly fixed varying rates for London, the larger centres of population and rural and other areas.

*Basis of Wage Rates.*—In view of the intention of the Acts the levels of the rates fixed are themselves of some interest. The best standards by which the rates may be judged are, perhaps, Mr. Seebohm Rowntree's "poverty line" and "human needs" figures. It will be found that the majority of trade board rates fixed for the lowest grades of workers in the trades concerned fall much nearer to the "poverty line" than to the "human needs" figure. In a very few cases only does the rate reach the latter figure. This fact leads to the consideration of the nature of the rates for "special classes" fixed by rather more than half the Boards.

These rates, higher than those fixed for the lowest grades of workers, apply to workers in skilled occupations. While such rates are still minima for workers of the class to which they apply, they may, but do not necessarily, diverge from the strictest form of the minimum wage and tend to encroach upon the field of general wage regulation. Indeed, as will be seen from a comparison of the basis of the 1909 Act with that of the 1918 Act, the spirit of the latter Act was considerably broader than that of the earlier, and was intended to meet the recommendation of the Whitley Committee that trades not sufficiently organised for adequate self-government should be provided with the means of regulation by the establishment of Trade Boards. The Act of 1909, however, remains the "principal Act," and within the narrower limits of the intention of that Act there is scope for the fixing of differential minima for the varying grades of workers within a trade.

Mr. Rowntree's "poverty line" figure (pre-War) was 26s. per week for a man. His "human needs" figure was 35s. 3d., thus leaving the substantial figure of 9s. 3d. per week as a margin between the necessities of the merest animal existence and the rather austere reasonable needs of a human being. Owing to the rise in the cost of living this margin would be nearly twice as great in 1926. It is hardly tenable that the purpose even of the Act of 1909, much less that of 1918, was limited to the fixing of "poverty line" wages where the trades concerned could reasonably pay something more, if only to skilled workers. Where, therefore, as has happened in the case of most of the boards, the lowest rate fixed has been much nearer to the "poverty line" than to the "human needs" figure, a board may, without departing from the strict principles of the minimum wage, proceed to fix higher rates for workers of greater skill than the lowest grade up to the level of the latter figure. This view appears to be upheld by the clause of the Agricultural Wages Regulation Act of 1924—the only case in which Parliament has given guidance as to the basis on which minimum wages should be fixed—which provides that "in fixing minimum rates a committee shall, so far as practicable, secure for able-bodied men such wages as in the opinion of the committee are adequate to promote efficiency and to enable a man in an ordinary case to maintain himself and his family in accordance with such standard of comfort as may be reasonable in relation to the nature of his occupation."

In so far as trade boards have fixed special rates which range beyond the "human needs" figure, it may be admitted that they have begun to enter the field of wage-regulation rather than minimum wage-fixing. Such rates, however, are unusual, are almost invariably agreed between the employers' and workers' representatives on the board, have been fixed for the convenience of the trade as a whole and have resulted in the prevention of friction which might otherwise have occurred between employers and employed. (J. J. M.)

**TRADE CYCLE.**—The phrases trade cycle, business cycle and cyclical fluctuation of trade are all convenient methods of labelling those alternating upward and downward sweeps in the vol-

ume of business activity which have constituted, for at least a century and perhaps more, one of the outstanding phenomena of the modern business world. The most obvious manifestations of the trade cycle are a quasi-rhythmical fluctuation, extending over several years, in the level of prices, the level of money profits and the level of employment.

In the absence of satisfactory statistics, it is difficult to be sure how far there occurs a corresponding fluctuation in the level of production and consumption, *i.e.*, in the real income of the community affected. While it is certain that these latter quantities fluctuate to some extent, it seems probable (a) that the fluctuations in output are less intense than the fluctuations in prices, (b) that the output of ordinary goods for immediate consumption fluctuates as a rule far less than the output of instrumental or constructional goods (typified by iron and steel), and (c) that the fluctuations in output do not entirely synchronise with the fluctuations in prices, but that, in the later stages of a "boom" of prices, production may cease to make any significant advance, while in the later stages of a "depression" of prices production may make a marked recovery.

Nor is it safe to dogmatise about the length of the trade cycle, or about the degree to which its phases synchronise in the leading industries and the leading industrial countries. Before the War there were indications that the normal period of the cycle had shortened from about 10 to about 6 or 7 years. The dates of "crisis" or turning-point from boom to depression, during the past century, are for England 1825, 1836, 1847, 1857, 1866, 1873, 1882, 1890, 1900, 1907, 1913, 1920; while in the United States the booms of the late 'eighties and 'nineties were prolonged, somewhat precariously, to 1893 and 1903 respectively. Again, the post-War boom, which in England and America broke in 1920, was prolonged in Germany till 1923; and while the recovery in America from the great slump of 1921 has been rapid and complete (with a slight set-back in 1923), recovery in England has been partial and slow. Again, the change-over from depression to prosperity, or prosperity to depression, does not affect all trades at the same moment, or even effect these in the same order.

In the main, however, it still seems to be fair to describe the trade cycle both as a *general* movement and as a rhythmical one; and any explanation of its causes must take these two factors into account. Very many such explanations have been offered,—too many to expand or criticise fairly in the course of a short article. It must be enough to set out and classify certain roads of thought, as it were, along which economists have been led to travel in search of the truth. It must be understood that these roads are not mutually exclusive, but that they intersect and partially coalesce, so that most writers traverse parts of more than one of them. Any comments made must be taken to reflect the tentative views of an individual writer and not to embody the *ex cathedra* pronouncements of economic science, which in this matter, as in so many others, are still to seek.

#### FOUR METHODS OF APPROACH

*The Psychological Approach.*—The first road leads into the domain of psychology. We are invited to find the chief explanation of the trade cycle in the nature of Man himself, and especially of those men who are responsible for conducting and controlling the operations of modern industry, commerce and finance. These business leaders are bound together not only by their business dealings but by ties of sentiment and environment: they operate, necessarily, in an atmosphere of uncertainty: and any error of forecasting which they make, whether of an optimistic or of a pessimistic kind, is apt to be magnified by their mutual contact into a great wave of erroneous judgment, which gathers strength for a time and then breaks, yielding place to an equally exaggerated movement in the opposite direction. There seems to be little doubt of the importance of this factor both in aggravating the amplitude of the trade cycle and in moulding it into its quasi-rhythmical shape. But we must be on our guard against supposing that all decisions made by business men to vary the scale of their purchases or their output are erroneous. Many

such decisions are clearly in the true interest of those who make them, if not of society as a whole. And it may be incumbent on us to enquire whether even erroneous decisions did not have their starting-point in some real and rational cause.

*The Monetary Approach.*—The second road leads into the tangled wood of monetary theory. Those who follow it lay stress on the dependence of the scale of industrial activity on the general level of prices, and on the dependence of the latter, in its turn, on the monetary policy of the Govt. and the banks. The independent leaders of business are advantaged during a period of rising prices, because the rise in many of their money costs of production (such as debenture interest, salaries and in some degree wages) lags behind the rise in their money receipts. They are accordingly both enabled, and furnished with a real inducement, to expand the scale of their operations: and owing to their habit of concentrating their attention on the movement of the price of *their own products*, the inducement is likely to seem greater to them than it actually is. Conversely, in times of falling prices, business men are both disadvantaged by the relative fixity of some of their money costs, and believe themselves to be more disadvantaged than they are: and they are impelled therefore to contract the scale of their operations. These price-movements, if left unchecked, act *cumulatively* in both directions; for as long as prices are expected to go on rising, business men continue to rush in to buy; and as long as prices are expected to go on falling, business men continue to liquidate their stocks of goods, and to refrain from replenishing them.

Now modern currency and banking systems, even when anchored to a gold standard, are of such a kind that, unless consciously operated with another end in view, they permit considerable play to these price movements. Indeed they exaggerate them by displaying an excessive timidity in altering those rates of interest whose magnitude has an important effect in determining the volume of loans issued by the banks, and consequently the volume of purchasing power put, in the form of cheque currency, into the hands of the public. In the last resort, therefore, it is held, both the unhealthy activity and speculative excesses of the period of boom, and the wasteful stagnation of the period of depression, are due to a faulty loan-policy on the part of the banks, or a faulty currency policy on the part of the Govt. or a combination of the two.

One objection to this explanation in its cruder forms is that the level of prices depends not only on the quantity of purchasing power issued to the public by the Govt. and the banks, but on the willingness of the public to *use* the purchasing power when it has got it; and that it does not seem certain that this latter factor, especially in a time of deep depression, when everybody is determined to hoard money rather than spend it, is entirely explicable in monetary terms or controllable by monetary means. Nevertheless, there seems little doubt that a monetary policy consciously aimed at keeping the general price level approximately stable, would do a good deal to damp down the violence of the trade cycle; and a policy of this kind has apparently been followed with some success by the Federal Reserve Board in the United States during the years 1922-5.

*Instabilities inherent in an Economic Process.*—The third and fourth groups of roads lead to an examination of certain *real*, as opposed to merely monetary or psychological, features of modern industry. The third group runs through a landscape of *physical* and *technical* features, the fourth through a landscape of *legal* and *social* ones. Let us consider the former by asking the question, "What rational reasons are there why industry as a whole should automatically increase and diminish the scale of its output?" and glancing at three possible lines of reply.

(1) Because of a self-renewing rhythm in its real costs of production. During the later stages of a depression there is a progressive advance in the effectiveness of labour, a progressive writing-off of inflated capital charges, a progressive overhauling of methods of technique and organisation, which breed renewed activity. During the later stages of a boom there is a progressive recourse to inferior instruments of production, a progressive utilisation of over-tired and recalcitrant labour, wasteful methods of management and inferior business leadership, which ultimately breed collapse.

(2) Because of variations, due to fluctuations in the bounty of nature, in the amount of agricultural produce offered in exchange for the products of industry. Normally, the effect of good harvests is to stimulate industry and of bad harvests to depress it: but there seem to be exceptional cases (as perhaps in 1920) where an overabundance of agricultural products leads to such a fall in their price as to impair seriously the purchasing power of agricultural producers over the products of industry, and so to induce industrial depression. Many attempts have been made to connect the trade cycle directly with a cycle of crop-yields dependent on meteorological phenomena: the most famous is that of Prof. W. S. Jevons to connect the supposed ten-year period of the trade cycle with the sun-spot period, and the most recent that of Prof. H. C. Moore to establish an eight-year period in economic affairs, depending on the behaviour of the planet Venus. Without accepting any such views, it is possible to hold that harvest variations, through their influence on the demand for transport and in other ways, frequently exercise an important influence in moulding the shape and the intensity of the trade cycle. It follows that the more numerous the sources of supply of any crop and the greater the facilities for carrying it over from year to year, the better for industrial stability; and it has been suggested in certain quarters that governmental purchase and storage of the leading crops would assist materially in the process of industrial stabilisation.

(3) Because of variations in the intensity of the desire for the fixed instruments of production and transport,—buildings, machinery, railways, ships, etc. These instruments are large and expensive: they take a long time to construct, but once a batch of them is constructed, it will serve to satisfy the increased needs of the community for many years. Investment in such instruments is therefore discontinuous, and their rate of output especially variable; and variations in the prosperity of the trades making them react severely on other trades. The rate of investment in instruments depends a good deal on the progress of technical invention, and it is tempting to connect a good many of the booms of the last century with inventions, e.g., that in England in 1847 with railway-building, that of 1900 (especially in Germany) with electric transport, etc.

It has been suggested that to counteract this cause of fluctuation, governments (both central and local), transport companies and even manufacturing firms should plan ahead their programmes of constructional work, and put them into operation so far as possible when times are slack.

*Instability Resulting from Organisation of Industry.*—We come finally to certain legal and social features of modern industry which may be held to promote instability of prices and output.

(1) There is first the fact of *competition*, which aggravates miscalculation, since individual producers do not gauge correctly the share of an increased market which will fall to their own lot, nor the effect which their rivals' action will have in driving up their own costs of production. It might be hoped, therefore, that the progress of the movement toward the formation of "trusts" and combines would damp down the violence of the trade cycle; but so far it is difficult to be sure that this hope has been fulfilled, partly because it is not always in the interest of combinations to promote stability, and partly because they are apt to interpret stability as stability of prices, which is not always consistent with stability of output and employment.

(2) There is secondly the *wage-system*, which may lead to a real disharmony between the interests of the employing class, which dictate the course of production, and those of society as a whole. For generally speaking the employer has more interest in intensifying production during a boom and curtailing it during a depression than the workman, who suffers during the boom from speeding-up and during the depression from unemployment.

(3) Finally, there is the *unequal distribution of wealth*, which in the view of many writers leads to a chronic tendency to "over-saving," manifesting itself during the boom in the construction of more instruments than will be able ultimately to find remunerative employment, and during the depression in, among other things, a piling-up of idle bank-balances. The remedy proposed is to increase the purchasing-power of the wage-earner, whose desire for necessities and comforts is held to be steadier and more elastic than the desire of the rich for luxuries and instrumental goods.

It remains to add that much work has been done in recent years, especially in America, in compiling statistical data concerning the trade cycle, and attempting to forecast its course. The more accurate the forecasts can be made, and the more widely business men act upon them, the greater will be the extent to which the course of the trade cycle is smoothed and evened out under the influence of the forces of instructed self-interest.

R.)

**TRADE FACILITIES.**—In Great Britain the trade facilities scheme formed part of the remedial measures laid before the House of Commons by the Coalition Government of the United Kingdom in the autumn of 1921. Prices were then at their lowest; trade was acutely depressed; and unemployment had reached an alarming figure. The policy of the Government, as explained by Mr. Lloyd George in the House of Commons on Oct. 19 1921, was to find a remedy by expediting the restoration of trade. One of the factors retarding the recovery was the difficulty experienced in raising capital, and it was proposed to use the credit of the Government to overcome this obstacle.

The Trade Facilities Act of 1921 empowered the Treasury to guarantee the principal and interest, or either the principal or interest, of loans for capital purposes, subject to certain conditions. The Treasury were only to act after consultation with an advisory committee; it must be demonstrable that the business was calculated to promote employment in the United Kingdom; the proceeds of any guaranteed loan must be used solely for carrying out works of a capital nature and must be spent in this country. No loans could be made by the Treasury, but with the aid of the Government's credit the applicant would of course be able to borrow his requirements on exceptionally favourable terms. Under the original Act the aggregate amount to be guaranteed was fixed at £25,000,000, but by subsequent legislation the amount has been added to from time to time. The Act of 1926 raised the total to £75,000,000. Similarly the period of operation has been extended to March 31 1927.

*Results of the Scheme.*—The extent to which advantage has been taken of the scheme affords some indication of the stimulus which it has given to industry and to employment. The quarterly return issued for the period ending Dec. 31 1925 gives the total figure of guarantees approved by the Treasury, after deduction made on account of applications sanctioned but subsequently cancelled by the applicants, at over £63,000,000. The greater part, in fact something over two-thirds of the whole, has been given for enterprises in Great Britain. A remarkable proportion has gone to the shipping industry, mainly for new shipbuilding. A considerable percentage has also been allocated for railway development, the London underground group alone having obtained some £12,500,000 for improvements and extensions. Another prominent category is electrical propositions both at home and overseas. Unquestionably, therefore, the undertaking of many projects of diverse kinds has been expedited through the operation of the Acts, and they have thus served their purpose. Doubts have, however, been felt in some quarters as to the repercussions of the stimulus so applied. Shipping interests, for example, have expressed some anxiety as to the effect, at a time when the industry is peculiarly depressed, of the ship-building programmes which have been embarked upon as a result of the cheap capital thus made available.

A cognate scheme relating especially to imperial development and arising out of the discussions at the Imperial Economic Conference of 1923, has also been embodied in the Trade Facilities Acts (Act of 1924). The Treasury has been empowered, subject to certain terms and conditions, to make a contribution of an amount not exceeding three-quarters of the interest payable in the first five years of the currency of a loan raised in the United Kingdom by or on behalf of any public utility undertaking in any part of the Empire overseas. An important condition requires that the expenditure must be in anticipation of expenditure which would normally have been incurred at a later date. The scheme has currency for three years from its commencement—i.e., to May 14 1927, and the maximum amount payable by the Treasury is not to exceed £5,000,000. (W. CL.)

**TRADE FORECASTS.**—The expressions "trade forecast," commonly used in Great Britain and "business forecast," commonly used in the United States, are synonymous and, unless qualified, refer to the outlook for business as a whole in a given country in the immediate future for, say, a period of not more than a year or a year and a half. The terms "trade" and "business" are used in their broadest sense to include all branches of economic activity, such as agriculture, mining, manufacture, forestry, building, transportation and wholesale and retail trade. General forecasts of business as a whole are, of course, frequently supplemented by specific forecasts for sections of a country and for industrial groups, individual commodities, security markets or money conditions.

**The Typical Period.**—A forecast, whether general or specific, begins properly with an appraisal of conditions at the time of forecast and follows with a prediction of the direction and magnitude of the movement during the immediate future. Such a forecast may include estimates of prospective variations that are expected to appear with the round of the seasons, and the "normal," or long-time, growth that is expected from one year to the next assuming no disturbing influences. But estimates of seasonal variation and the growth element are not usually the factors of primary importance in a business forecast. The factor of primary importance is the nature of the ensuing "cyclical" movement of business or (if objection is made to the use of the term "cyclical") of the "state of trade."

The notion of a "business cycle" is at the basis of the great majority of business forecasts. (See **TRADE CYCLE**). Some business forecasters contend that business cycles are "periodic"; in other words, they hold that an approximately uniform time interval exists between a given phase of each business cycle and the same phase in the succeeding cycle. They base their forecasts upon the assumption of a fixed period, but they are not all in agreement as to the length of the period. Periods of 10, 8, 7, and 3 or 4 years have found support by different investigators. In the United States, for example, between 1870 (when that country resumed specie payments) and the World War severe business disturbances—during which a period of high or expanding business was followed by a period of contracting business—occurred in 1882, 1887, 1890, 1893, 1895, 1899, 1903, 1907, 1910 and 1912. Some of these years of business disturbance were followed by deep business depression (1884-5, 1893-4, 1896-7 and 1908); others by more moderate depressions (1904 and 1911), and still others by periods of less pronounced business recession, not ordinarily thought of as veritable depressions (1887-8, 1891 and 1900). Forecasters who base their forecasts upon the assumption of a "typical" cycle of standard form, amplitude and length (say 40 months, with 25 months of expanding business and 15 months of contracting business) are obliged, in practice, to depart from the rigidity of the concept in order to make it consistent with history and to provide for the probability that future business cycles may prove to be as variable as those of the past.

**Variations in Time.**—A second group of forecasters finds it more in accordance with business history to drop the concept of a "typical" periodic cycle and substitute therefor the concept of a business cycle of *variable* time, duration, amplitude (intensity of cyclical deviation from normal) and form (reflected by the steepness of the recovery from depression and ascent into prosperity and by the swiftness of the subsequent decline). If this concept be adopted, forecasts must be made on the basis of uniformities or regularities other than time-duration, amplitude, or form of the cyclical movements. Regularities have, in fact, been found in the sequence of the movements of various statistical series reflecting speculation, business and credit, a sequence which has been found to be much less subject to variation than the cycle itself. This sequence has been found in the United States, England, France and Germany and it affords a valuable means of forecasting the movements of series of one type from a knowledge of the movements of series of other types. Such forecasting requires a careful interpretation of the economic significance of the situation reflected by the various types of

movements and hence the sequence itself is not a sufficient means of forecasting. In other words, a mechanical application of the sequence doctrine may not give satisfactory results. Particularly, the systematic regulation of credit by banking authorities, gold movements and other factors operating on the money markets, must be considered.

**Other Methods.**—A third group of forecasters holds that (a) the alternation of business prosperity and depression and (b) the sequences between movements of individual statistical series are both so irregular that the concept of a business cycle should be discarded. In making business forecasts the members of this group rely upon general economic analyses of the current situation and evaluations of the movements which they find, at any time, to be in progress. This group is, perhaps, less homogeneous than the others and its methods are so general as to make them difficult or impossible of classification.

A fourth group of forecasters rely upon mechanical statistical relationships (which can seldom be interpreted adequately in economic terms) as a basis for their predictions. For instance, forecasts have been made on the assumption that "action and reaction are equal and opposite" in business fluctuations as well as in mechanics. Frequently, such forecasts are accompanied by general economic analyses that make them on their face indistinguishable from those of the third group.

**Development of Forecasting.**—Business forecasting has received its greatest development in the United States and the description, just given, of methods of forecasting is based primarily on usage in that country. Systematic forecasting, however, is being developed in England, France, Japan and other countries. Forecasting is an outgrowth of statistical studies of business fluctuations rather than of the application of general theories of the causes of such fluctuations. A condition for satisfactory business forecasting is the existence of adequate business statistics, promptly available at weekly or monthly intervals. This condition has been more fully met in the United States than in any other large commercial country.

**Agencies Publishing Forecasts.**—Various agencies in the United States and some in other countries publish more or less definite forecasts of general business conditions. Among such agencies in the United States are banks, journals, Government bureaux (e.g., Foreign and Domestic Commerce, Agricultural Economics, Federal Reserve Board) and commercial forecasting organisations. In other countries, forecasts are published by certain journals, but regular forecasting services have only recently been established outside the United States. There is such a service however, in Japan. A development has been the establishment of economic services under the auspices of Harvard University (Harvard Economic Service) in the United States, under the London School of Economics and Political Science and the Department of Economics of the University of Cambridge (London and Cambridge Economic Service) in England, under the Institute of Statistics of the University of Paris (Mouvement Général des Affaires en France et en Divers Pays) in France, and under the Institute of Statistics of the University of Padua (Italian economic index) in Italy. These four services are associated.

**TRADE UNIONS** (see 27.140).—This article gives (1) an account of the British trade union movement since 1911; (2) particulars of trade union growth in other countries and (3) an account of the international organisation of the movement; a further section deals with the movement in the United States.

## I. THE UNITED KINGDOM

The outstanding features of British trade unionism since 1911 have been:—

(1) The improved organisation of and extension of trade unionism amongst "general workers" and women, in agriculture and on the railways, and in the public services and professions;

(2) The increasing importance of the trade unions in the community, and in the administration of legislation;

(3) The consolidation of trade union forces through the processes of amalgamation and federation;

(4) The growing authority of the executive body of the Trade Union Congress.

The policy of the trade unions and their attitude towards the problems of industry, have been influenced by many different factors, among them the abnormal conditions of War time and the post-War period (with its prolonged trade depression), the advent of a Labour Government, and developments of economic theory in the Labour movement.

#### GROWTH OF MEMBERSHIP

Trade union membership increased before and during the World War, especially among women, the curve rising rapidly during its later years, and culminating in the peak period of 1920, after which it progressively declined during the years of depression, recovering during 1924.

#### ! Trade Union Membership

All trade unions, registered and unregistered, in Great Britain and Northern Ireland

| Year | No. of Unions at End of Year | Membership (000's Omitted) |        | Total (000's Omitted) | Percentage Increase or Decrease on Previous Year |
|------|------------------------------|----------------------------|--------|-----------------------|--------------------------------------------------|
|      |                              | Male                       | Female |                       |                                                  |

| 1919 | 1,346                        | 6,595                      | 1,325  | 7,920+                | 21.3                                             |
| 1920 | 1,358                        | 6,988                      | 1,340  | 8,328+                | 5.2                                              |
| 1921 | 1,241                        | 5,610                      | 1,003  | 6,613-                | 20.6                                             |
| 1922 | 1,190                        | 4,712                      | 868    | 5,580-                | 15.6                                             |
| 1923 | 1,135                        | 4,590                      | 815    | 5,404-                | 3.7                                              |
| 1924 | 1,155                        | 4,720                      | 811    | 5,531+                | 2.2                                              |

The highest degree of organisation amongst women is to be found in the cotton industry, where about 62% of the women workers are in the unions. In the bleaching and dyeing trades, which are closely associated with the cotton industry, 50% of the women are organised; in the boot and shoe trade 48%; in printing, paper and bookbinding, 36%; in the wool textile trades, 22%; in linen and jute 28½%. Amongst shop assistants and clerks, and in the food, drink and tobacco trades, on the other hand, which employ in all over 750,000 women workers, the degree of organisation is very small. Only 8% of the women shop assistants and clerks are members of unions and 2% of the female employees in the food, drink and tobacco trades.

Before the War the battle for the recognition of trade unionism was really won and the principles of trade unionism, which had been laid down primarily by the craft unions, were applied on the one hand by the larger body of semi-skilled and unskilled workers, and on the other hand by the "black-coated proletariat"—the salaried employees and professional people, such as public servants, draughtsmen, actors, commercial travellers, teachers and journalists.

After 1914 new organisations arose and others which existed precariously before the War were put upon a firm foundation. Some of the new bodies, such as the Bank Officers' Guild, have not as yet affiliated with the Trades Union Congress, but they nevertheless exist for avowed trade union objects. The National Federation of Professional, Technical, Administrative and Supervisory Workers was established in order to bring together for consultation and common action the various organisations of non-manual workers.

The steady growth in trade unionism before the War may be attributed partly to a trade prosperity and partly to a recognition amongst almost all grades and types of workers of the need for effective organisation. Certain legislation, such as the Trade

Boards Act, 1909, and the National Insurance Act, 1911, strengthened the position of the trade union movement.

The increased membership during the War was partly due to the influence of higher wages—which invariably result in enlarged trade union membership. As the War went on, high hopes were held out of a brighter future for the workers; the workers themselves, whose services, the community had realised, were essential to the prosecution of the War, and to the satisfaction of the nation's needs, visualised more clearly their power in the State and saw in trade unionism a weapon to enable them to maintain in the time of peace the place their services had won for them in time of War. But there were other factors operating. Particularly in the munition trades, trade union membership became virtually compulsory. The Government itself, and a large number of employers actually encouraged workers in the larger industries to join a union. Towards the end of the War, the publication of the reports of the committee on employers and employed (better known as the Whitley Committee) and their adoption by the Government, gave a new importance to the organisations of employers and workers, and in their desire to promote the establishment of joint industrial councils (and interim industrial reconstruction committees, when the joint industrial council was not possible), members of the Government emphasised the importance of effective organisation. (See INDUSTRIAL RELATIONS.)

As a consequence of these various influences, between the early days of the War and the year 1920, the membership of trade unions doubled, reaching the figure of 8,328,000, of whom 6,988,000 were men and 1,340,000 women. During this time the number of women trade unionists was actually trebled. Similarly there had been phenomenal increases in the membership of unions catering for the less skilled workers. Before the War, what are known as the general labour unions had already become factors of some importance in the trade union movement. During the War period, their strength increased rapidly. The number of organised non-manual employees also rose much above the pre-War level, and included workers hitherto practically unorganised.

But just as rising wages are closely followed by a rise in the curve of trade union membership, so unemployment and falling wages are accompanied by a decline in it. The onset of the grave trade depression after the temporary post-War boom led to a decline of trade union membership amounting to 20% in the first 12 months and a further 15.6% in 1922, the total roll of trade unionists falling in two years from 8,328,000 to 5,580,000. The net loss on the previous year's figure was less than 4%, whilst during 1924 there was a net increase.

The backwash of the trade depression, and the disillusionment which followed the shattered dreams of post-War "Reconstruction" had spent themselves. The trade union movement had shed the temporary passengers, and those who entered its ranks through the abnormal influences of the War and early post-War periods; and a definite attempt to stem the tide and re-create a powerful trade union movement had begun to take effect. The established minimum trade union membership may be taken as being about 5½ millions, an increase of over a million on the figures of 1913. The year 1924 saw a beginning of a slow but steady increase on this minimum, though there was a further small decrease in the number of women trade unionists.

#### Affiliated Membership of Trades Union Congress

|      | No. of Trade Unions | No. of Members |
|------|---------------------|----------------|
| 1911 | 127                 | 1,645,507      |
| 1912 | 127                 | 1,987,354      |
| 1913 | 135                 | 2,217,836      |
| 1914 | 190                 | 2,866,077      |
| 1915 | 192                 | 2,677,357      |
| 1916 | 227                 | 2,850,547      |
| 1917 | 235                 | 3,082,352      |
| 1918 | 262                 | 4,532,085      |
| 1919 | 266                 | 5,283,676      |
| 1920 | 215                 | 6,505,482      |
| 1921 | 213                 | 6,417,910      |
| 1922 | 206                 | 5,128,648      |
| 1923 | 194                 | 4,369,268      |
| 1924 | 203                 | 4,328,235      |
| 1925 | 203                 | 4,342,982      |

The affiliated membership of the Trades Union Congress followed the general trend of the aggregate trade union membership as will be seen from the preceding table. Though in 1925 the affiliated membership was but two-thirds that of the peak year 1920, it was practically double that of 1913.

The broad distribution of trade union membership amongst the industries of Great Britain is indicated in the following table:—

|                                      | Number of Unions | Membership at End of 1924 |
|--------------------------------------|------------------|---------------------------|
| Mining and Quarrying                 | 113              | 966,031                   |
| Metal, Engineering and Ship-building | 115              | 678,974                   |
| Textile                              | 281              | 609,968                   |
| Building                             | 48               | 335,334                   |
| Transport                            | 49               | 1,028,348                 |
| Public Employment                    | 272              | 318,765                   |
| Paper, Printing, etc.                | 24               | 187,087                   |
| Clothing                             | 30               | 165,111                   |
| Woodworking, Furnishing              | 32               | 94,380                    |
| General Labour                       | 20               | 511,206                   |
| All other                            | 176              | 639,930                   |

From 1924 onward the General Council has pursued a policy of propaganda, first by means of a national "back to the unions" campaign and then by special activities with a view to the spread of trade unionism amongst women agricultural workers respectively, whilst individual unions, though impoverished as the result of the long depression, renewed their efforts to secure an increasing membership.

#### TRADE UNIONS AND THE COMMUNITY

The growth of trade unionism has meant that the trade unions have become an integral part of our social machinery. This development has taken two main lines. In the first place, the trade union is now regarded as the normal machinery for the prevention and settlement of disputes. The State itself regards trade unions as responsible representative bodies. They are called into consultation by the Government in times of dispute, and their leaders are invariably the spokesmen and advocates of the workers before Courts of Enquiry set up under the Industrial Courts Act. They express the workers' point of view before Royal Commissions and Government committees, and the Labour members of such investigating bodies are drawn from the ranks of organised Labour. On the Whitley Councils in the Government services, the staff side is conducted by the representatives of the Civil Service unions. The joint industrial councils concerned with services in which local authorities are interested are, like all other such councils, composed on the workers' side of trade unionists. The trade unions have won for themselves a definite place in the system of "industrial government" and they are parties to the industrial agreements which govern the relations between employers and employed, lay down the methods of consultation and negotiation, and determine wages and working conditions.

*Share in State Administration.*—In the second place, the trade unions play an important part in the administration of certain legislation. When the Trade Boards Act, 1909, was passed it was applied to four trades in which trade unionism was weak, and at the outset the interests of the workers were in large measure in the hands of the National Anti-Sweating League and the Women's Trade Union League. But trade unions have since been extended to almost every industry. The Trade Boards Act of 1918, which amended and broadened the original Act, extended the minimum wage to trades to which hitherto the Act of 1909 had not been applied. (See TRADE BOARDS.)

The recent growth of the general labour unions is partly due to the opportunities which the establishment of more trade boards has given them to organise the workers; particularly in the case of women workers, where, however, the increased trade union membership has been obscured since the War by the withdrawal from industry and from the trade unions of women who came into the labour market to make good the shortage during the War.

The Corn Production Act, 1917, set up agricultural wages boards on which the representatives of the unions catering for agricultural workers sat. The boards were, under the law, engaged in establishing binding rates of wages. The unions obtained a new status, and the Corn Production Act gave a new impetus to the difficult task of organising these workers. When the Act was repealed in 1921 the trade unions had nearly 300,000 members employed in agriculture. In 1924 the Labour Government re-established the system of wages boards, and the unions concerned are represented on the boards, and participate in the administration of the Act.

The National Insurance Act of 1911 opened the door to trade union participation in its administration. Part I. of the Act dealt with health insurance and provided, in general, for the payment of State benefit under the scheme by approved societies. Many trade unions formed trade union approved societies to administer the health insurance scheme, and these have become important agencies in the conduct of this vast system of social insurance. A National Association of Trade Union Approved Societies exists to protect the interests of the constituent societies, and played a prominent part in the opposition to Part I. of the Economy Act of 1926, which reduced the State contribution to health insurance. The insurance activities of the unions have not only associated them with the working of an important piece of legislation, but have consolidated, and in some cases strengthened, the position of the unions with their own members.

Part II. of the National Insurance Act, 1911, dealt with unemployment insurance, but the scheme was a limited one. Compulsory insurance against unemployment was widely extended by the Unemployment Act of 1920 to cover nearly 12,000,000 workers. Provision was made whereby trade unions which ordinarily distributed out-of-work pay to their members should, subject to certain conditions, be allowed to administer the State scheme, and pay the State benefit to their members, for which service the unions received an allowance. Many unions applied this provision of the Act, but the reduction of the administration allowance from 1s. per week's benefit paid to sixpence led to some unions ceasing to administer the Act. In 1926, however, there were 15 unions with a membership of 1,126,700 still operating under Sect. 17 the Act of 1920, and in order to secure a common policy on matters affecting their position under the Unemployment Insurance Acts, the unions concerned set up a standing committee, which acts in co-operation with the Trade Union Congress General Council.

On the local employment committees and juvenile advisory committees attached to the employment exchanges and on the juvenile choice of employment committees of local authorities, the trade unions are represented; whilst since the establishment of "uncovenanted" and "extended" benefit they have been actively associated with the employment exchange rota committees for the administration of this form of benefit.

#### WAR WORK OF THE UNIONS

During the progress of the War the trade unions were intimately connected with the conduct of certain phases of national affairs. In March 1915 the Government came to an agreement (known as the Treasury Agreement) regarding the production of munitions, which included compulsory arbitration, the relaxation where necessary of trade union rules, and the limitation of profits in munitions industries. From then onwards, the unions were called upon to assist in accelerating the production of munitions, in administering certain of the controls which were instituted (such as those in the cotton and wool textile industries) and in the selection of men for war service. Parts of the Treasury Agreement were embodied in the Munitions Acts, and offences under these Acts, except such as were brought before the ordinary courts, were dealt with by specially appointed munitions tribunals. Each tribunal consisted of a chairman, with either two or four assessors, drawn equally from panels representing employers and workers respectively. These bodies played a great part in the administration of the Munitions of War Acts, and dealt with many thousands of cases against both employers and employees.

A National Labour Advisory Committee on War Output was established early in the War, together with local labour advisory boards in each munitions area. The National Committee was replaced in 1917 by the Ministry of Munitions Trade Union Advisory Committee, which was divided into three sections representing the engineering group, the shipbuilding group and the general labour group. A special women's trade union advisory committee was also appointed in the same year to advise the Ministers on all questions relating to women's work. Towards the end of the War, further steps were taken arising out of unofficial strikes in Coventry and Birmingham which, though speedily settled by the trade unions concerned, led to the appointment of a Government committee (on which there was trade union representation). This committee, which was critical of the policy of the Ministry of Munitions, recommended the establishment of a joint committee of employers and trade unionists, and the closest possible consultation, both nationally and locally, upon changes and developments of policy—a proposal which the Government accepted.

The recruiting of men for the army was in the early stages of the War left entirely to the War Office. But haphazard recruitment led to the crippling of essential industries, by the withdrawal of skilled men in considerable numbers, and to industrial unrest. It was, therefore, found advisable to bring trade unions into consultation on questions of recruiting. The recruitment of miners for the army was dealt with by committees composed of representatives of the miners and mineowners, with a chairman appointed by the Government.

Similarly, when the Government imposed its control over certain industries, the trade unions primarily concerned played an active part. The cotton and wool textile controls may be taken as an illustration. The cotton control board (set up in 1917) determined the amount of machinery which was to be run upon other than Government orders, and imposed a levy upon concerns working full time to pay out of work benefit to workers employed by firms suffering from the operation of the raw cotton order (which prohibited the purchase of cotton except under licence) and the control board. The wool control board, also instituted in 1917, consisted of eleven representatives of the trade unions, the employers and the War Office contracts department respectively. All wool was purchased by the Government and the board controlled the allocation of supplies and organisation of the civilian trade. When the consumers' council was set up under the auspices of the Ministry of Food, the trade unions were officially represented on it.

After the War, these various forms of organisation came to an end; but they had given a new standing to the trade union movement. Since 1918 the chief administrative activities of the trade unions have been in connection with Health Insurance, Unemployment Insurance and Trade Boards.

#### THE CONSOLIDATION OF TRADE UNIONS

The movement towards consolidation of trade union forces which was very pronounced between 1911 and 1926, was partly the outcome of the theoretical teaching of syndicalism and guild socialism, but it was largely due to experience and the hard facts of economic life.

Federations have changed from loose alliances to negotiating bodies acting on behalf of the constituent unions. This development is seen in the case of the Engineering and Ship-building Trades Federation and the Miners' Federation of Great Britain, both of which have achieved responsibility for national negotiation. In Nov. 1910, on the initiative of the Dockers' Union, the National Transport Workers' Federation was formed comprising practically all the Unions catering for workers employed in water-side transport, including seamen, dockers and carters.

*The Triple Alliance.*—The Triple Industrial Alliance which came into existence in 1914 was, in effect, a federation consisting of the Miners' Federation of Great Britain, the Transport Workers' Federation and the National Union of Railwaymen; it was thus composed of two bodies which themselves were federations and a large industrial union. The associated bodies were the unions

concerned in the key industries of coal and transport, and the formation of the alliance created some consternation. But the only occasion when the Triple Alliance decided to embark upon industrial action was during the coal stoppage of 1921, when the Alliance issued notices calling a strike in support of the miners. The notices, however, were postponed and then withdrawn on April 14 (Black Friday). The effect was to destroy the alliance, but the association of the railway, transport and mining unions continued, as they formed one of the "groups" constituted by the General Council of the Trades Union Congress. In 1925 attempts were made, largely on the initiative of the Miners' Federation, to establish a new alliance on a broader basis than the Triple Alliance; but as membership of the new alliance involved in some cases an alteration of the rules of certain unions, and as the implications of the proposed association needed careful consideration, the completion of the alliance hung fire, and certain unions definitely decided against co-operation.

*Textile Trades.*—In June 1916 the National Association of Unions in the Textile Trade was established. Of the 36 unions of which the Association is composed, 20 represent wool textile workers. The Association, however, includes, besides workers engaged in manufacturing and finishing processes, those engaged in the textile machinery trade, and the skilled workers engaged in the maintenance of plant. The Association appoints the workers' representatives on the joint industrial council of the wool textile industry. But the association also exists to promote trade union amalgamation in the industry; and to secure co-ordination in the case of disputes. In the summer of 1925, during the stoppage which occurred in the wool textile industry, the workers' side of the dispute was handled by the association and not by the separate unions, and when the dispute was referred to an industrial court, the workers' case was submitted by the association on behalf of all the unions concerned.

*General Workers.*—The General Labourer's National Council (established in 1908) developed in 1917 into the National Federation of General Workers, composed of the seven chief unions of general workers with an aggregate membership of over 800,000.

*Building Trades.*—The National Building Trades Council (representative of the 13 chief unions in the building industry) formed the basis for the National Federation of Building Trade Operatives established in 1918. This body has become the recognised organ for consultation and negotiation with the National Federation of Building Trade Employers. In 1925, however, the Amalgamated Union of Building Trade Workers withdrew from the Federation, which thus no longer represented the whole of the organised workers in the industry.

*Foundry Trades.*—Early in 1918 the Federation of Foundry Trades came into existence to promote amalgamation of the unions in the industry, deal with demarcation disputes, and secure joint action wherever possible. It included about a dozen unions with a total of between 50,000 and 60,000 members. Three of the unions in the federation—the Friendly Society of Ironfounders, the Associated Ironmoulders of Scotland and the Amalgamated Society of Core-makers, in 1922 merged to form the National Union of Foundry Workers.

*The G. F. T. U.*—The General Federation of Trade Unions has changed its character. It does not now take any active part in trade union disputes and negotiations or in the work of promoting closer industrial organisation. The G.F.T.U. was formerly the medium of communication between the British and Foreign Trade Union Movements, but since 1920 the General Council of the Trades Union Congress has been the representative British organisation in the international Federation of trade unions. The chief work of the G.F.T.U. is in connection with dispute pay. Contributing associations pay contributions to the Federation on the basis of their membership, and receive, when involved in a stoppage of work, benefit to be paid to their members. In 1925, there were 118 unions affiliated to the Federation with a total membership of 830,316 members.

The following table gives the number and gross membership of federations in Great Britain and Northern Ireland at the end of each year:—

| Year | No. of Federations | Approximate Total Membership |
|------|--------------------|------------------------------|
| 1913 | 125                | 4,370,000                    |
| 1914 | 137                | 4,730,000                    |
| 1919 | 134                | 9,896,000                    |
| 1920 | 114                | 10,744,000                   |
| 1921 | 108                | 8,623,000                    |
| 1922 | 93                 | 6,232,000                    |
| 1923 | 90                 | 5,654,000                    |
| 1924 | 87                 | 5,331,000                    |

## AMALGAMATIONS

Trade union amalgamation was hampered by the Trade Union Act of 1876, which required that each of the organisations concerned should carry a motion for amalgamation by a two-thirds majority of the whole membership. In 1917, however, the legal requirement was reduced to a 50% vote. Some important amalgamations followed upon this alteration of the law.

*The N. U. R.*—One of the most striking amalgamations which was carried through prior to the Act was that which resulted in the establishment of the National Union of Railwaymen. Up to 1913, when it was formed by the merging of three independent unions, the railway unions had not yet won full recognition from the companies. The N. U. R. shares with the Associated Society of Locomotive Engineers and Firemen, which is a craft union, and the Railway Clerks' Association, the representation of railway employees, and with certain other unions, the representation of the workers in the railway engineering workshops. The N. U. R. illustrates both the tendency towards larger scale organisation, for its object is "to secure the complete organisation of all workers employed in or in connection with any railway in the United Kingdom"; and also the incomplete success it has achieved and the difficulties inherent in this policy. In time, the Associated Society of Locomotive Engineers and Firemen and the Railway Clerks' Association may possibly merge into the National Union of Railwaymen; but the organisations of the Engineers, Boilermakers, Carpenters and other railway shopmen, for which other unions cater, is one which raises a conflict of principle which has not yet been settled.

*Iron and Steel Trades.*—A new method of consolidation was adopted in the establishment of the British Iron and Steel and Kindred Trades Association and the Iron and Steel Trades Confederation in 1917. The former was, in effect, a new union, which the various participating unions influenced their members to join. These unions admitted no further members, all new members joining the B.I.S.K.T.A., and they transferred their powers to the Iron and Steel Trades Confederation, which conducts the work of organisation and negotiation. When all the members of the participating unions have been transferred to the B.I.S.K.T.A., it will assume the duties and powers of the confederation, which will then cease to exist.

*Engineering Trades.*—The Amalgamated Engineering Union, one of the largest post-War amalgamations, illustrates the consolidation of craft unions. The nucleus of the present union was the Amalgamated Society of Engineers, with which nine other craft unions engaged in engineering coalesced in 1920. The A.E.U. catered for skilled mechanics but has now opened its ranks to include other grades of workers.

*Other Trades.*—Jan. 1921 saw the establishment of the Amalgamated Society of Woodworkers, the nucleus of the new organisation being the Amalgamated Society of Carpenters and Joiners. In the same year, the Amalgamated Union of Co-operative and Commercial Employees and National Warehouse and General Workers' Union merged to form the National Union of Distributive and Allied Workers. The Amalgamated Union of Building Trade Workers formed at the beginning of 1921 was an amalgamation of the Operative Bricklayers' Society, the Manchester Unity Operative Bricklayers' Society and the Operative Stonemason's Society. In 1922, the Dock-Wharf, Riverside and General Workers' Union formed the nucleus of an amalgamation under the name of the Transport and General Workers' Union, uniting the National Union of Dock Labourers, the Scottish Union of Dock Labourers, the National Union of Vehicle Workers, the United Vehicles (which was an amalgamation of the Tramway Workers and the Licensed Vehicle Workers) and several other unions. Originally established as the Gasworkers' and General Labourers' Union, this union became the National Union of General and Municipal Workers, when in July 1924 it absorbed the National Amalgamated Union of Labour and the Municipal Employees' Association. In 1923 the National Federation of Women Workers was merged in the National Union of General and Municipal Workers. Discussions have since taken place with other unions, e.g., the Workers' Union and the Transport and General Workers' Union as to the possibility of further amalgamation. Other post-War amalgamations include the United Garment Workers (1920) which unified several sectional and local bodies, the Union of Post Office Workers formed (1920) by the combination of three unions, and subsequently enlarged by the absorption of half a dozen other organisations of post office employees, the National Union of Blastfurnacemen (1922) which took the place of the National Federation composed of five local Unions of blast furnace workers, and the National Union of Sheet Metal Workers (1921) which combined a number of small federated societies of steel metal workers and braziers.

Federations are becoming more powerful; in some cases they pave the way to the amalgamation of some of their constituent bodies; in others the federations themselves become amalgamations. The following table shows that during the five years 1920-4,

there was a net reduction in the number of trade unions amounting to about 200, due in no small measure to the effect of amalgamation.

| Year | New Unions Formed (other than by amalgamation) | Reductions due to |               | Net increase or reduction |
|------|------------------------------------------------|-------------------|---------------|---------------------------|
|      |                                                | Dissolutions      | Amalgamations |                           |
| 1920 | 119                                            | 33                | 82            | +4                        |
| 1921 | 45                                             | 73                | 85            | -113                      |
| 1922 | 28                                             | 40                | 36            | -48                       |
| 1923 | 16                                             | 42                | 16            | -42                       |
| 1924 | 26                                             | 18                | 14            | -6                        |

These various amalgamations have been pursued with the definite object of securing unified organisation over an extending field, so as to render negotiations more comprehensive and possible action more effective. The Trades Union Congress has passed frequent resolutions dealing with the need for improved organisation, and in 1924 adopted as its policy the reduction in the number of trade unions to "an absolute minimum," and "as far as possible, organisation by industry with every worker a member of the appropriate organisation."

## THE CENTRAL ORGANISATION

In 1919, proposals were submitted to a special Trades Union Congress for the replacement of the old Parliamentary Committee of the Congress by an enlarged executive body, for the creation of a machinery of co-operation between the Congress and the Labour party, and for the establishment of joint administrative departments under the auspices of the congress and the Labour party. These general proposals put forward in the interim report of a co-ordination committee, which had been appointed by the Parliamentary Committee, were accepted by the special congress. The full scheme was submitted to the Congress in the following year. The Parliamentary Committee was superseded by the General Council, a body composed of 32 members representing the 17 groups of trades and industries into which the affiliated membership of the Congress was divided, including two women representing the women membership of the Trades Union Congress.

The following table shows the organisation of the General Council into groups:—

| Group No. | Groups                                     | No. of Members on General Council | No. of Unions | No. of Members of Affiliated Unions (1925-6) |
|-----------|--------------------------------------------|-----------------------------------|---------------|----------------------------------------------|
| 1         | Mining and Quarrying                       | 3                                 | 9             | 840,543                                      |
| 2         | Railways                                   | 3                                 | 3             | 454,924                                      |
| 3         | Transport (other than railways)            | 2                                 | 9             | 397,126                                      |
| 4         | Shipbuilding                               | 1                                 | 4             | 122,850                                      |
| 5         | Engineering, Founding and Vehicle Building | 3                                 | 23            | 394,051                                      |
| 6         | Iron and Steel and Minor Metal Trades      | 2                                 | 21            | 153,932                                      |
| 7         | Building, Woodworking and Furnishing       | 2                                 | 16            | 349,658                                      |
| 8         | Printing and Paper                         | 1                                 | 13            | 167,665                                      |
| 9         | Cotton                                     | 2                                 | 37            | 234,864                                      |
| 10        | Textiles (other than Cotton)               | 1                                 | 17            | 152,307                                      |
| 11        | Clothing                                   | 1                                 | 8             | 90,428                                       |
| 12        | Leather and Boot and Shoe                  | 1                                 | 5             | 86,868                                       |
| 13        | Glass, Pottery, Chemicals, Food, etc.      | 1                                 | 16            | 186,534                                      |
| 14        | Agriculture                                | 1                                 | 1             | 30,000                                       |
| 15        | Public Employees                           | 1                                 | 10            | 150,627                                      |
| 16        | Non-Manual workers                         | 1                                 | 8             | 62,845                                       |
| 17        | General workers                            | 4                                 | 5             | 475,700                                      |
| 18        | Women workers                              | 2                                 |               |                                              |

It will be seen that the mining and quarrying group is the largest in point of membership, the second being the group known as general workers.

This organisation is carried further by the establishment of group committees. For administrative purposes the 17 trade groups were formed into six group committees as follows:—

(a) mining and quarrying, railways, transport; (b) shipbuilding, engineering, iron and steel, building; (c) cotton; other textiles, clothing, leather; (d) glass, pottery, etc., agriculture, general workers; (e) printing, public employees, non-manual workers; (f) the two women members and three members appointed by the General Council from organisations with women members.

The Congress also accepted in 1920, as did the Labour party conference of 1921, proposals for the establishment of a national joint council consisting of the chairman and secretary and three members of the General Council of the Trades Union Congress, the Executive Committee of the Labour party and the Parliamentary party, making 15 members in all. This body was set up to deal with questions affecting the Labour movement as a whole. The Congress and conference, further, agreed to the establishment of four joint departments—(a) research and information, (b) press and publicity, (c) international and (d) legal. This new central machinery resulted in a great expansion of activities by the General Council of the T. U. C. itself and by the Council in conjunction with the political Labour movement. In 1925 the standing joint committee of industrial women's organisations included 25 national organisations, and represented over 1,000,000 organised working women.

The General Council of the T. U. C. deals with a wide range of questions and its authority continues to increase. It has instituted a standing trade boards advisory council, composed of representatives of organisations catering for workers covered by the Trade Boards Acts. It has its education committee which has concerned itself with the problem of adult education, whose proposals, approved by the Trades Union Congress in 1925, were designed to assist in the promotion of educational facilities for trade unionists, and had been arrived at in agreement with Ruskin College, the Education Department of the Co-operative Union, the Labour College, the Workers' Educational Association and the National Council of Labour Colleges. The object of the proposals was "to provide working class education in order to enable the workers to develop their capacities and to equip them for their trade union, Labour and Co-operative activities generally, in the work of securing social and industrial emancipation." Early in 1926, the Countess of Warwick handed over her estate, Easton Lodge, Dunmow, in Essex to the General Council of the Trade Union Congress for use as a Labour College and as a labour centre generally.

The General Council has taken an increasingly important part in large industrial disputes. At the Hull Congress of 1924, its hands were strengthened in this matter. In the event of a breakdown of negotiations in a dispute, however, "the deadlock being of such a character as to directly or indirectly involve other bodies of work-people affiliated to the Trades Union Congress in a stoppage of work or to imperil standard wages and hours and conditions of employment, the council may take the initiative by calling representatives of the unions into consultation, and use its influence to effect a just settlement of the difference." Before this resolution was carried, the General Council had, in fact, intervened by mediation or the granting of moral and financial support, in disputes in which affiliated societies were concerned. In the prolonged Boilermakers' dispute in 1924, in the Dock Workers' dispute, the Tramway dispute in the London area, the Southampton Shipyard dispute, and the Building Trade dispute in the same year, the General Council used its good offices. But the adoption of the resolution of Sept. 1924 placed greater authority in the hands of the Council. On the occasion of the dispute in the coal industry in July 1925 the General Council appointed a special industrial committee (which has since become a standing body) and took a very prominent part in the negotiations which led to the temporary settlement. The Industrial Committee in Aug. 1925, intervened in the dispute in the wool textile industry which had culminated in a stoppage of work.

In conjunction with the Labour party and the Miners' Federation of Great Britain the General Council established a commit-

tee early in 1925 to prepare a policy for the coal industry, and the proposals of this joint committee were submitted to the Royal Commission on the Coal Industry set up by the Government after the coal settlement in July 1925. After the publication of the Royal Commission's Report, the General Council, through its Industrial committee resumed its consultations with the Miners' Federation and was associated closely with the Federation during the course of negotiations. Finally, it declared a large scale sympathetic strike (erroneously called a general strike) and for the first time in its history directly conducted an industrial stoppage. This, however, was called off in a few days (see STRIKES AND LOCKOUTS).

The Council also takes active steps to deal with difficulties which arise between affiliated unions. For this purpose the General Council acts through its disputes committee. In 1925 this committee held no less than 32 meetings. The disputes which occur between unions vary in their character.

An important and developing side of the activities of the General Council is the forging of closer bonds with the trades and labour councils which exist in large numbers up and down the country. Before 1895 trades councils were represented at the annual Trades Union Congress. But from that date until 1924 there was no direct contact between these local representative bodies of trade union branches and the T. U. C., though the Trades councils (many of which are local Labour Parties) were affiliated to the Labour party and may send delegates to its annual conferences.

After the establishment of the General Council, efforts were made to remedy this defect in organisation, and in 1925 a model form of constitution for trades councils was worked out, arrangements made for the publication and circulation of special literature on trade unionism, and a regular monthly statement from the general council to the trades council was inaugurated. At the end of 1924, there were 476 trades councils known to be in existence in Britain, including industrial sections of local Labour parties. In 1913 the number was 328. From 1913 to 1924 the aggregate affiliated membership rose from 1,481,000 to 2,219,000, the latter figure representing about two-fifths of the total membership of trade unions.

But perhaps, the most significant amongst the activities of the General Council, is its efforts under the instructions of the Trades Union Congress to promote and assist trade union amalgamation on the lines of organisation by industry. Though the General Council has from time to time brought together unions for discussion of the possibilities of amalgamation, it has realised that much more is needed than empirical action of this kind. Judged by the results the efforts to bring about amalgamations of the General Council cannot be regarded as successful, though it is still too early, having regard to the real difficulties of amalgamation, to pronounce this work as a failure. Its real importance, however, lies in the persistent and painstaking labour to reach an ideal, and the certainty that, if need be, larger powers will ultimately be given to the general council to deal with the problem. It is significant that the consolidation of forces should be regarded as of paramount importance.

*Finance.*—Up to 1923, the affiliation fee of each union affiliated to the T. U. C. was 1d. per member per year. In that year the fee was raised to 3d., payable quarterly on the full membership, including probationary and free members. The increased fees were required principally for publicity purposes and to maintain *The Daily Herald*, the organ of the British Labour movement. In addition to the ordinary affiliation fees, each union contributes £1 per thousand members towards the fee payable to the International Federation of Trade Unions. Congress affiliation fees in 1924-5 amounted to £21,088. The affiliation fee to the International Federation of Trade Unions was £4,450.

#### THE INDUSTRIAL AND THE POLITICAL MOVEMENTS

As the Trades Union Congress really gave birth to the Labour party, it is natural that close relations should always have existed between the industrial and political sides of the Labour movement. From 1905 onward there existed a joint board representing the Parliamentary Committee of the T. U. C., the Executive

Committee of the Labour party and the Management Committee of the G. F. T. U. (which also owed its existence to the T. U. C.). The members of the board were the secretary and three members from each of the three bodies. But in 1914 the Congress decided to dissolve the tripartite joint board and to establish a new one representing the Parliamentary Committee of the Trades Union Congress and the executive committee of the Labour party. At the Congress of 1917 steps were taken to ensure close co-operation between the two committees. Regular joint monthly meetings were arranged, following the separate meetings of the two committees. These joint meetings continued, and joint action has been taken on innumerable occasions. Large questions demanding considerable enquiry are usually referred to joint committees of the two bodies. The great developments which have taken place in the activities of the General Council with all the implications they involve, led in 1926 to an understanding whereby the Council shall have research, press and international staffs under its direct control, but arrangements were made for the closest co-operation.

#### GENERAL POLICY

During the period from 1911 to the outbreak of the War, there was considerable labour unrest due largely to the steadily rising cost of living, but receiving inspiration in some degree from the intellectual ferment in the world of labour. Syndicalism, though never a potent force in the British trade union movement prompted and encouraged the movement towards militant industrial unionism. The persistent propaganda of the Socialist societies had also begun to influence the outlook of the trade unionist. From about 1910 it is clear that the trade union movement, judged by the resolutions of the T. U. C. was socialist in temper. It was definitely in opposition to capitalism and to private ownership of the means of production. The socialism, however, to which trade unionism gave adhesion, was essentially collectivist; but a closer association with the problems of industry and a widening knowledge of the world of industry led to a sense of dissatisfaction with the arid doctrines of undiluted collectivism, which came indeed to be described as "State capitalism." Syndicalism, whilst it never commanded a large measure of support, did, by its emphasis on the workers' right to control, indicate the possibilities of a policy which whilst providing for public ownership escaped the charge of "State Capitalism" by the adoption of the principle of democratic control.

*Shop Stewards Movement.*—During the pre-War years, however, these ideas had not clearly emerged. The effects of State regulation during the War, however, powerfully assisted in swinging active trade union opinion round to a sympathetic appreciation of the essential doctrines of Guild Socialism. Moreover, the new importance of the Labour element in the community gave birth to new aspirations, and to the claim that the workers should enjoy increasing responsibility and power in the actual conduct of industry. One of the most powerful groups of influences which moulded the minds of organised Labour were those connected with the conditions of War-time employment. In the chief industries, the unions were parties to arrangements for the increase of output and the avoidance of stoppages of work. But the abnormal psychology of War time, unsympathetic and short-sighted administration in the munitions areas, and the knowledge that the union executives were in a position of great difficulty, led to unofficial strikes and to the evolution by the workers of unofficial machinery for securing the removal of grievances.

Shop committees sprang up in the munitions industry, and in the engineering trades they became influential organisations. Shop stewards became the real leaders of the rank and file in matters affecting the day to day lives of the workers in industry. This new re-organisation within the industrial Labour movement—the creation of the circumstances in which the trade union executives were inevitably placed—proceeded swiftly and to a considerable extent effectively. It was unknown to the general public until it had established itself. It was spontaneous—an obvious method of satisfying the need for some rapid local machinery which could deal with grievances in the workshop. It is true, of course, that

there grew up a literature embodying the philosophy of the shop stewards' movement, but it gave a justification to the movement rather than an impetus to its growth. This rank and file movement strengthened the demand for self-government in industry.

It spent itself during the War. With the end of the War, it lost the passion which had sustained it; but the value of shop committees and of shop stewards was recognised, and, first in the engineering industry and subsequently in others, the unions adopted this machinery and grafted it on to their organisation.

In the meantime, the policy of self-government in industry had become crystallised, and since the War the T. U. C. has accepted the policy of public ownership combined with the association of the workers in the government and control of industry. The application of this policy may be seen in the bill prepared by the Railway Clerks' Association for the nationalisation of railways, and subsequently in the scheme for the future of the coal industry placed before the Coal Commission of 1925-6 by the Miners' Federation, with the full support of the T. U. C. General Council and the Labour party.

*Reactions of the Russian Revolution.*—The Bolshevik revolution in Russia had its reaction upon the British Trade Union movement. Some of the leaders of the shop stewards' movement embraced Communist doctrines, and when the Red International of Labour Unions was formed by the Moscow Communist International attempts were made to secure the adhesion of trade union bodies to the R. I. L. U. Such British bodies as are affiliated, however, are not national unions, but sectional and local organisations. Under the inspiration of communist doctrines the National Minority movement was organised, as what may be called the communist wing of the trade union movement. It consists of groups and sections of trade unions, and the voice of its spokesmen is heard on the floor of the T. U. C. in favour of an advanced policy and in support of a policy for closer relationship between Britain and Russia. The General Council of the Congress itself sent a delegation to Russia towards the end of 1923, and the Council has actively supported a policy of friendship between Britain and Russia, and has used every effort to bring about an understanding between the International Federation of Trade Unions and the Russian Trade Unions.

The National Unemployment Workers' Committee movement established during the period of heavy post-War unemployment is directed largely by people of Communist sympathies. It is impossible to assess the influence which Communism within the trade union movement is exercising; but numerically the number of trade unionists definitely attached to the Communist party of Great Britain is small. The factors which have led a minority of trade unionists into the ranks of Communism and the National Minority movement (which it may be said includes a considerable portion of workers who could not be described as Communists) have led a far greater number to a realisation of the need for a more vigorous industrial policy for the trade union movement. The establishment of the General Council of the T. U. C., the enlargement of its powers, and the large extension of its activities were an expression of this need. One of the first problems, however, is that of the organisation of trade unionism; for clearly the success of any industrial policy must depend in the last resort on the efficiency of trade union organisation.

*Industrial Unionism.*—So long ago as 1910 and 1911 the Congress committed itself to the principle of organisation by industry, and in 1911 urged the Parliamentary Committee to call conferences of the different industries "with a view of amalgamating the several trade unions connected with each industry." This somewhat crude principle was interpreted in a reasoned resolution adopted by the Congress in 1918, when it was agreed (a) that the organisation of an industrial union should allow for the maintenance within the union of each district craft combination and for the possibility of federating such combinations with like bodies outside the union for specific purposes; and (b) that every craft union and general Labour union should allow sectional combinations within the union, on industrial or occupational lines, so as to facilitate inter-union federations, and, if circumstances require, the transfer of a section to any more appropriate union.

In 1922 the Trades Union Congress instructed the General Council to make an enquiry into the present organisation of the trade union movement as a necessary basis for a policy of closer unification. The Hull Congress of 1924 led to the appointment of a special committee by the General Council to tackle the question of trade union organisation, and the present attitude of the Council on this matter is contained in an able memorandum by Mr. W. M. Citrine, submitted to this Committee and published in the annual report of the Congress for 1925. The General Council has boldly admitted the defects of the existing trade union structure and method—the prevailing sectionalism, the competition between different unions for workers, varied rates of contributions and benefits, demarcation of work and the lack of a co-ordinated policy. It is certain that the conflicting claims of pure and unadulterated industrial unionism, occupational unionism, federal unionism and craft unionism, will necessitate some composite method which, within the framework of the industry, permits variety of organisation to meet the needs of special crafts and groups. (A. Gb.)

## II. THE UNITED STATES

The period from 1910 to 1926 has been an eventful one for trade unionism in the United States. Since 1910 notable changes have taken place in the philosophy and practices of both employers and trade unions. Business has made some progress in the stabilisation of industry and the standardisation of its products. A number of employers have made the protection of their employees' welfare a part of their labour management activity, while others have engaged actively in an "open shop" campaign against trade unions. In this period the courts have been unusually liberal with their use of the injunction and have rendered a number of decisions against the activities of trade unionism. The period has also seen the World War with its effects on the labour movement.

In response to these and other developments, American labour has evolved some remarkable trade agreements; providing for union-management co-operation, industrial courts and unemployment insurance. The trade unions have also entered the banking field and established schools and colleges for their members.

In 1912 Congress authorised the formation of a Federal Commission on Industrial Relations. This commission's investigations lasted three years. It examined 500 witnesses and prepared a report very favourable to organised labour. This was the first time in American history that a government commission has unhesitatingly pronounced the trade-union movement a fundamental and indispensable public institution.

The Clayton Anti-trust Act which became a law in 1914 declared that human labour is not a commodity and that labour organisations are not to be construed as illegal conspiracies in restraint of trade. It also limited the use of the injunction in labour disputes. This Act was hailed as labour's Magna Carta, but subsequent court decisions have left the legal status of trade unions quite as uncertain and unsatisfactory as if no such Act had been passed.

When the United States entered the World War, the American Federation of Labour pledged its unequivocal support to the Government. Placing organised labour thus at the service of the nation secured for it for a time a degree of national prestige and freedom to expand which could not have been secured by many years of agitation and strikes. The War Labour Board guaranteed to labour the right to organise, the basic eight-hour day and the living wage. In 1916 the American Federation of Labour membership was 2,072,000; by 1918 it had risen to 2,726,000; by 1919 to 3,260,000, by 1920 to a maximum of 4,078,000. Since then it has declined to 2,877,000 showing that 40% of the War-time gains have been retained. With the falling off of immigration due to the War and the passage of the immigration restriction law of 1921, the power of American trade unionism has been increased, for while certain trades had been able to unionise the immigrant, he has been a constant barrier against organisation.

Since 1910 the trade unions have had a number of set-backs at the hands of the courts. The lower courts have been free in granting injunctions against trade-union action during strikes. Of these the injunction against the railway shopmen in 1922 is one of the most sweeping decrees issued in labour disputes. The Supreme Court also handed down several decisions which greatly hamper trade-union activity. In 1915 the U.S. Supreme Court in the case of *Coppage v. Kansas* (236 U.S. 1) held unconstitutional a Kansas law preventing employers from threatening to discharge their employees unless they renounce union membership.

Two years later in the *Hitchman Coal and Coke Co. v. Mitchell* case (245 U.S. 229) the Supreme Court held that, where an employer has required his employees to sign a contract that they will not join any labour union, it is illegal to attempt to organise them. In 1921 in *Duplex Printing Company v. Deering* (254 U.S. 443) the Supreme Court held that a secondary boycott was unlawful and the employer had a right to a restraining injunction under the Sherman Act as amended by the Clayton Act. The same year in *American Steel Foundries v. The Tri-City Central Trades Council* (257 U.S. 184) the Court held that it is illegal during a strike for more than one picket to be stationed at a point of ingress or egress to a plant. In *Truax v. Corrigan* (257 U.S. 312), 1921, the Court declared unconstitutional an Arizona law, modelled on the British Trades Disputes Act, which sought to place a limit on the free use of the injunction. The law attempted to declare illegal any injunction seeking to restrain workers from ceasing to patronise or from advising others to cease patronising an employer against whom they were on strike. In 1922 the Court in *U.S. Mine Workers v. The Coronado Coal Company* (259 U.S. 344) held that a trade union may be sued under the Sherman Act for damages done to an employer during a strike.

During these years a remarkable development in productive efficiency has taken place. No reliable estimates have been made, but the gain is notable in nearly all industries. This increase in efficiency has had causes other than the technological development, though the latter is the most important factor. The U.S. Department of Commerce in 1921 began a systematic campaign for the elimination of waste in industry. Since then it has conducted some 900 conferences of business men which have set 229 committees at work on various phases of the programme. The department set out to eliminate not individual or wilful wastes, but those wastes which can be eliminated only by co-operative action of the industry or community.

The growth of efficiency in industry is probably the most important development for trade unionism which has taken place during the period since 1910. Its effect has been like that of a two-edged sword. The mechanisation of industry has eliminated the necessity of skilled labour. American trade unionism is founded upon the philosophy of the craft and the crafts are being eliminated, one by one. The great problem before the American labour movement to-day is the organisation of the unskilled, machine-tending, factory workers. On the other hand, the growth of efficiency has brought higher wages. The greater the output per worker, the greater will be the employers' wage-paying capacity and the higher will be the wages which both union and non-union labour can successfully obtain. Wages have shown considerable increases both in money rates and in purchasing power during the post-War years. The American Federation of Labour has taken note of the increases in efficiency and the elimination of waste and at its last convention went on record as approving the movement towards waste elimination. It further pointed out that if social equality and industrial stability are to be obtained, the hours of labour must be decreased and wages increased in proportion to the progress that is made in increasing production.

During the years 1910-26 there has developed a new capitalistic philosophy and a new set of labour management practices. Many employers have voluntarily set out to do for their employees the very same things which trade unions have been doing for their members. These welfare practices have originated

mainly in the unorganised industries and have greatly retarded the extension of trade unionism therein. These new labour policies have set out to protect the standard of living of employees in various ways. Some employers are voluntarily paying higher wages; some are introducing profit-sharing schemes, bonuses, wage premium plans, education, housing, community betterment, plant restaurants, vacations with pay, etc. Shop committees, works councils and systems of employee representation have also been inaugurated. Some of these plans have been undertaken in the interests of greater production. Some represent an effort to retard the development of trade unionism by making it less necessary. But regardless of motive, much good has come from them. However, there are a few shortcomings which should be noted. Such welfare work tends to tie the worker to his job and reduce his independence and gives no guarantee of permanence. A change in corporate management or a decline of prosperity may cause abandonment of the arrangements. The workers did not secure the introduction of these plans, and, being unorganised, they cannot enforce their continuance. Nor can collective dealing with company unions be considered a substitute for collective bargaining with trade unions. Even where a company union may negotiate a wage scale for the plant, its bargaining power is inferior to that of a trade union. The latter has greater membership, larger funds and more able leadership. The American Federation of Labour has felt the strength of this new development especially strong in certain industries, and has begun a careful study of the subject so that its members may better meet the issue in their organised work.

In Oct. 1919 President Wilson summoned to Washington 15 representatives of labour, 15 of capital and 15 of the public for the President's Industrial Conference. At this conference the employers stood solidly for the open shop and the labour group stood as solidly for the closed shop and collective bargaining. The conference broke up without accomplishing anything. The unsuccessful conclusion of the conference and the steel strike of the same year solidified opinion on both sides and the employers started what is known as the Open-Shop drive. The movement seemed to spring up spontaneously in practically every industrial centre in the country and was vigorously pushed by employers' associations, its purpose being to weaken trade unions, prevent unionisation and convince the public of the desirability of the open shop and the anti-union campaign.

In 1926 a number of important industries were conducted under the principles of the open shop, or the "American Plan," as its proponents often call it. Among the most important open-shop industries may be mentioned the steel, textile, automobile, book and job printing, machinery and paper industries, also the San Francisco building industry. The open-shop movement has proved a great set-back to trade unionism, but it is not known whether it has spent itself and its influence is waning.

In Feb. 1923 a co-operative plan between the Baltimore and Ohio Railroad and the railway shop crafts was undertaken with a programme for the elimination of waste, the betterment of shop organisation and the stabilisation of employment. Under the plan the unions were to be made necessary parts in the shop administration on a par with the superintendents. Regular joint local and district meetings are held. The local federated shop crafts committee meets with a committee of the shop management. The officers of the system federation and of each craft meet with the head of the road's maintenance of equipment department. After the success of this plan was demonstrated in one shop, the co-operative scheme was extended to all the shops of the Baltimore and Ohio Railroad. Recently similar arrangements have been made on the Chicago and Northwestern Railway, the Canadian National Railways and the Chesapeake and Ohio Railway. This plan has the official endorsement of the American Federation of Labour. The union management co-operation plan as adopted on these railways is a logical extension of the principle of collective bargaining and is based on a labour policy which accords the labour movement a positive

function in the conduct of industry. It is the trade union's answer to the open-shop drive, the welfare work and company union policies.

The period 1910-26 has seen also a remarkable series of trade agreements which have set up a system of private industrial law and a system of private unemployment insurance. A protocol signed in 1910 by the employers and the International Ladies' Garment Workers Union of New York City may be regarded as the first real constitution in the clothing industry. In the men's clothing industry, industrial government dates from the 1911 agreement between the Amalgamated Clothing Workers and the firm of Hart, Schaffner and Marx. This agreement set up a joint and impartial judicial machinery and specified the rights and duties of the two parties. Disputes between the parties are carried to a trade board and thence, if necessary, to a Board of Arbitration. Similar agreements have been made subsequently between an association of the remaining Chicago clothing manufacturers and the Amalgamated Union. Such judicial systems have also been established in the Rochester (New York) men's clothing industry, the New York City men's clothing industry and the ladies' garment industry of Cleveland. In all these courts the decisions are recorded, precedents are established and a body of industrial common law, not dissimilar to the early English common law, is gradually accumulating.

In 1923 the Amalgamated Clothing Workers and their employers in Chicago reached an agreement on the principle of an unemployment insurance fund. There are over 400 firms in the Chicago men's clothing market which employ about 35,000 workers. There are five boards of trustees, one each for the two largest firms, one for the remaining large concerns, one for the non-association houses and one for the contractors. One man is chairman of all the boards. The union has the same members on all the boards; but the personnel on the employers' side differs with each board. One insurance office keeps the books and carries on all the statistical work. The employer deducts the weekly premium of 1.5% from the wages of each employee and forwards the total amount, together with an equal amount as his own contribution, to the treasurer. Payments of benefits began in May 1924. Benefits to those out of work amount to 40% of the unemployed worker's average wage. The maximum benefit is \$20 a week and the combined wage and benefit for workers on part time cannot exceed \$50 a week. This unemployment insurance scheme was later applied in the New York men's clothing market, in the ladies' cloak and suit industry, the hat and cap industry and the fur industry of New York, as well as in the ladies' garment industry of Cleveland.

Workers' education began with the establishment in 1916 of a Workers' University in New York City by the International Ladies' Garment Workers Union. In 1926 there were workers' classes and study groups, under the direction of state federations, in over 300 industrial centres of 40 states, with some 40,000 students enrolled. Two resident labour colleges with permanent teaching staffs have been established, Brookwood College at Katonah, N.Y., and Commonwealth College at Mena, Arkansas. In addition, eight workers' summer schools with resident faculties—some in connection with regular universities—have been opened, and several universities have started workers' classes as part of their extension work. During the five years to 1926 no less than 350 scholars and university instructors have been associated with the movement. In 1921 this trade union educational work was placed under the supervision of the Workers' Education Bureau in co-operation with the American Federation of Labour. Nearly 30 books and pamphlets have been issued by the bureau and half as many more are in preparation.

Trade-union activity in the banking field began with the opening in 1920 of a Washington Bank in which the International Association of Machinists had acquired half interest. During the ensuing six years various labour organisations secured control of, or organised, over 30 banks with combined resources of well over a hundred million dollars. Many of the most prominent unions entered the banking business, but as yet there is considerable difference of opinion as to the desirability of this

new development. The American Federation of Labour has begun an investigation of the subject and at its last convention adopted a resolution calling attention to the "grave responsibility assumed by those who enter into these undertakings" and sounding a note of "emphatic caution because we appreciate the potentiality of labour banking and wish to promote its wise development." Trade-union leaders who are active in labour banking maintain that workmen's savings deposited in private commercial banks are used to promote the interests of business men and not the welfare of the labouring classes.

A number of trade-union leaders are sceptical of the desirability of entering into the banking business. They urge that banking is a foreign responsibility which will take time and attention away from the bargaining issue. Organisations which become prosperous in banking are apt to become bankrupt in unionism. It is further contended that there is a tendency for labour banks to violate safe banking principles. Interest payments have been generous. The temptation to loan to an employer who recognises the union and yields to its demands is grave and dangerous from the banking standpoint. As yet labour banking is a new and unsettled policy.

On Dec. 13 1924 occurred the death of Samuel Gompers who had organised the American Federation of Labour and had been its President for 43 years. He was succeeded by William H. Green of the Miners' Union. The passing of Gompers typifies the change that has been coming over the American labour movement. He was a pioneer leader who fought for the establishment of the movement, while Green is a business leader who has shown a desire to guide the already established movement into constructive and co-operative agreements between its membership and their employers. (J. R. Co.)

### III. INTERNATIONAL ORGANISATIONS.

After the War in practically all countries trade union membership stood at a much higher level than it had done before the War.

The table below shows the growth of membership in over 20 countries from 1910 onwards.

The table covers all the most important countries in the world except Russia, where figures are not available for the pre-War years, and China, Japan and India, where trade unionism was little developed before the War.

Reliable estimates are available for the following 20 countries (United Kingdom, Germany, U.S.A., France, Italy, Belgium, Holland, Denmark, Sweden, Norway, Finland, Switzerland, Spain, Austria, Hungary, Czecho-Hungary, Canada, Australia, New Zealand and Serbia). The total trade union membership was at the end of 1910, 10,835,000; 1914, 13,222,000; 1919, 32,680,000.

*Membership of Trade Unions at the End of the Years 1910-9*

| Country             | 1910      | 1911      | 1912      | 1913      | 1914      | 1915      | 1916      | 1917      | 1918      | 1919      |
|---------------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| United Kingdom      | 2,400,000 | 2,970,000 | 3,226,000 | 4,192,000 | 4,199,000 | 4,417,000 | 4,677,000 | 5,547,000 | 6,645,000 | 8,024,000 |

<sup>1</sup> Figures not available.

In 10 years, according to these figures, trade union membership had trebled, and more than doubled in five years. A small part of the rise is due to the greater completeness of the returns, and another small part (probably about 10%) to the natural growth of the population, but even allowing for these two factors, the growth of trade unionism was considerable and it was common to all countries.

In most countries during the first part of the War the growth of trade unionism was checked. The decline was substantial in Germany, Austria, Hungary, Italy and Czechoslovakia but in these countries the numbers began to increase in 1917. After the end of the War numbers increased rapidly, especially in the Central European States. In Europe the total membership at the end of 1919 was at least 26,000,000 as against about 8,500,000 at the end of 1910.

In the 30 countries of the world for which information is available the total membership in 1919 was 42,040,000, and in 1920, 48,029,000. If we take the figures for 1919, no less than 80% of the trade unions belonged to European countries. Of the remaining 7,979,000 members outside Europe, 5,985,000 belonged to the North American continent. Six countries—Germany, Britain, the United States, Russia, France and Italy accounted in 1919 for 33,500,000 members, whilst the remaining 24 countries accounted for only 8,750,000. Two-thirds of the total trade union membership was concentrated in four countries—Germany, Britain, the United States and France.

Prior to the World War the two chief organs of the International Labour movement were the International Federation of Trade Unions and the Second International, the former industrial and the latter political. After the War, early efforts were made to reconstruct the industrial and political Internationals.

*The Amsterdam International.*—The International Federation of Trade Unions (the I.F.T.U.) was reconstituted in 1919 following a Congress held at Amsterdam. It consists of the various national central trades union organisations affiliated, but the General Council includes three delegates from the "international trade secretariats," (i.e., representatives of the "trade internationals" such as the International Miners' Federation). The management of the I.F.T.U. is vested in the executive committee, the General Council and the Congress. The Executive Committee (or the Bureau, as it is often called) consists of the officers (i.e., the president, vice-presidents and secretaries) and meets six times a year. The General Council (often referred to as the Management Committee) is a larger and more representative body. The supreme governing authority is the Congress which consists of the General Council and the representatives of the affiliated national centres (e.g., the British Trades Union Congress). Representatives of the "trade internationals" take part

in congresses, but without the right to vote. Congresses have been held at Amsterdam (1919), London (1920), Rome (1922), The Hague (1922) and Vienna (1924). The affiliated membership of the I. F. T. U. since its re-establishment has been as follows: on Dec. 31 1921, 21,991,615; 1922, 18,185,531; 1923, 15,316,127.

The chief "trade internationals" are the metal workers (2,585,717), transport workers (2,091,840), miners (1,941,199), textile workers (1,326,030), building workers (938,940), factory workers (844,988), woodworkers (711,287) and commercial, clerical and technical employees (695,185). At the end of 1923, the total membership of the trade internationals was over 14,750,000.

The following statistics of membership of the trade union centres affiliated to the I.F.T.U. are the most recent available. Unless otherwise stated, they refer to the year 1924-5:-

<sup>1</sup> Unless otherwise stated these figures refer to 1923.

<sup>2</sup> 1924-5.

<sup>5</sup> The figures in brackets indicate the membership of organisations which, though not affiliated to the I.F.T.U. nevertheless adopt its platform.

<sup>3</sup> From a Communist source.

<sup>4</sup> Official Fascist Government Figure.

*The Red International.*—There are, in addition, a number of trade unionists who are linked with the Red International of Labour Unions which was brought to birth by the Communist International. The idea was, however, conceived at the Zimmerwald and Kienthal conferences. The R.I.L.U. was established in 1920 during the second congress of the Communist International, at which minority trade union representatives from various countries were present, when it was declared that "it is the duty of the working class to gather together all trade union organised forces with a powerful revolutionary class association, which, working shoulder to shoulder with the political organisation of the Communist International of the proletariat and in closest contact with this organisation, would be able to develop all its forces for the general victory of the social revolution and the establishment of a world Soviet Republic." It was also laid down that the International Federation of Trade Unions "because of its programme and tactics" could not "secure the victory of the proletarian masses in all countries." The first R.I.L.U. congress was held in July 1921, in Moscow, and has since continued its work in close association with the Communist International. Relations between the I.F.T.U. and the R.I.L.U. have been hostile. The British Trades Union Congress, however, has endeavoured to bring about an understanding, though without success.

It is not easy to ascertain the real strength of the affiliated membership of the R.I.L.U., but Losovsky, the secretary of the Red International, has analysed its membership as follows (see "*The World's Trade Union Movement*, 1925, pp. 244-5):—

The Red International of Labour Unions has eight types of affiliated organisations:—

1. National trade union centres embracing the whole trade union movement of their respective countries, such as Russia, with 6,400,000 trade union members; Bulgaria, 40,000; Greece, Egypt, 50,000; Persia, 20,000; Estonia, 25,000, and so on.
2. National trade union or regional revolutionary centres existing parallel with reformist centres and carrying on a struggle against them, our organisations being stronger than the reformist ones. Such are: France, with 480,000 members; Czechoslovakia, 300,000; Yugoslavia, 100,000; Java, 35,000; and so on.
3. National trade union centres playing a small rôle in comparison with the reformist trade union movement of their respective countries, as in Holland with 20,000 members; Belgium, 12,000; Germany, 150,000; the United States, 25,000; and so on.
4. National trade union centres identifying themselves with the principles of the R.I.L.U., but not affiliated thereto, as a result of the "White Terror," as is the case in Finland, 50,000; Rumania, 60,000; and so on.
5. Independent unions and unions formed of expelled members not belonging to the national trade union centres of their respective countries.
6. Minorities inside the reformist trade unions organised under the direct leadership of the Communist faction: Germany, Japan, Italy, Sweden, Denmark, etc.
7. Opposition blocs or minority movements co-ordinating the action of all left-wing elements both inside and outside the reformist and the Anarcho-Syndicalist unions of such countries as: the United States, Great Britain, Spain, Austria, the Argentine, Mexico and elsewhere.
8. Finally, there are the left-wing elements belonging to the unemployed committees (Great Britain), shop stewards committees, etc., generally supporting the R.I.L.U. policy."

It will be seen that no national trade union body representing the whole of the organised workers of any country, apart from Russia and certain small countries where trade unionism is an ineffective force, has associated itself with the R.I.L.U. and that outside Russia its chief support comes entirely from individual trade unions and minority groups, though Losovsky is at pains to point out that the figures of membership of the I.F.T.U. are swollen by the adherents of the R.I.L.U. It is not, however, the case, as stated by Losovsky, that "the strength of the R.I.L.U. and the I.F.T.U. is equal."

The position of trade unionism in the world, so far as it can be ascertained is given in the table on the preceding page. The figures are analysed according to the orientation of the respective national trade union centres, and unless otherwise stated, the figures refer to the year 1923.

**BIBLIOGRAPHY.**—The chief British publications are the *Labour Gazette*, published by the Ministry of Labour, the Reports of the

Chief Registrar of Friendly Societies and the *Industrial Directory* of the Ministry of Labour.

Important publications issued by the British Labour movement, which contain official decisions and a reprint of the leading documents and correspondence are the Annual Reports of the Trades Union Congress and the Annual Reports of the Labour party. These two bodies also publish *The Labour Year Book* (see issues for 1916, 1919, 1924, 1925, 1926). See also *The Labour Bulletin of Industrial and Political Information* (monthly). On the international side, information is available in the publications of the International Federation of Trade Unions, the Communist International and the Red International of Labour Unions.

**General Works.**—For the history, organisation and theories of trade unionism, the chief works are Sidney and Beatrice Webb, *The History of Trade Unionism* (new edition, 1920) and *Industrial Democracy* (new edition, 1920); C. M. Lloyd, *Trade Unionism* (new edition, 1921) (these works contain Bibliographies); G. D. H. Cole, *Organised Labour: An Introduction to Trade Unionism* (1924).

**International Movement.**—See also A. Losovsky, *Trade Unions in Soviet Russia* (1920), and *The World's Trade Union Movement* (1925), published by the National Minority movement. The Trades Union Congress is publishing a series of pamphlets on Trade Unionism in Action, of which two have appeared—*The Story of the Trades Union Congress*, and *The General Council of the Trades Union Congress, Its Powers, Functions and Work*. The Trades Union Congress published (1924) the Report of its delegation to Russia. The International Federation of Trade Unions is publishing an International Trade Union History of which two volumes have appeared—C. Mestens, *The Trade Union Movement in Belgium* (1925) and Walter M. Citrine, *The Trade Union Movement of Great Britain* (1926). For Germany, see S. Sanders, *Trade Unions in Germany* (1916), and for Ireland, W. P. Ryan, *The Irish Labour Movement* (1920).

**Special Studies.**—There are some special studies of trade unionism. See G. D. H. Cole and R. Page Arnot, *Trade Unionism on the Railways* (1917); E. Selley, *Village Trade Unions in Two Centuries* (1920); Mrs. Barbara Drake, *Women in Trade Unions* (1920); R. W. Postgate, *The Builders' History* (1923); Sidney Webb, *The Story of the Durham Miners and Industrial Negotiations and Agreements* (Joint Labour Publications Dept.); G. D. H. Cole, *Labour in the Coal Mining Industries, 1914-21*. On the legal side, see H. H. Slesser and Baker, *The Law of Trade Unions*. A shorter work is H. H. Slesser, *The Law Relating to Trade Unions* (1921). (A. Gd.)

**TRAFFIC PROBLEMS.**—Throughout the civilised world the countryman is being irresistibly drawn towards the great cities, which spread outwards, ring by ring, over the open fields, while the ancient core of the city on which millions of workers now converge retains the shape imprinted on it in mediaeval times when a small compact area amply sufficed.

## I. IN GREAT BRITAIN

*London.*—Although the difficulties thus created are by no means restricted to Greater London, where the population had risen from 7½ millions in 1911 to 7¾ millions in 1925, yet it is probably within this area that the typical problems present themselves in the most aggravated form. In 1923 the registrar-general published, for the first time, a report on the workplaces of residents in London and the five home counties. The preface reminds us that in a less highly organised and industrialised society localities may be self-sufficient, every residential group being supplied with its needs by members of the same groups in their working capacity. Such conditions were due to the dispersion of necessary service and production, which in the absence of transport facilities, had to be located in proximity to the population served. The subsequent development of transport and communications fostered a concentration which has changed the whole face of industry. The growth of great commercial centres calls for the concentration of an army of workers far beyond the residential capacity of their immediate neighbourhood; the housing deficiency is aggravated by the substitution of warehouses for dwellings in the centres, while the very development of transport which makes it necessary for the worker to live at a distance from his work has also made it possible for him to do so. Thus it happens that great masses of the population move in tides of daily ebb and flow, as evidenced in the City of London, whose night population of 13,709 expands thirtyfold during the day (416,150).

To gauge the magnitude of the traffic problem the following data may be of service. In the year 1904 a census was taken of vehicles of all classes passing 14 of the more congested points in London. The total reached was 291,930. In the year 1925 a

FIG. 1.—Diagram illustrating the gyratory system, in operation in Parliament Square, London.

count taken at the same 14 points gave a total of 458,376, an increase of 57.02%. The outstanding feature on the London streets is the motor-omnibus, of which in the year 1913 the number licensed was 3,664. By Jan. 1 1924, the number had risen to 5,311, and by Oct. 1 1925 to 5,502. In the year 1913 the passengers carried by omnibuses numbered 736,000,000; in 1924, 1,485,000,000; while in 1925 a total of 1,600,000,000 was computed to have been reached. The important part played by the London County Council's tramways can be estimated from the statement that their tramcars carry more than 1,000,000 passengers during the six busiest hours of the day. On the Victoria Embankment 400 tramcars pass every hour.

Expressed in millions the numbers of passengers carried by the various forms of transport in London have been estimated as follows:

| Year       | Suburban Trunk Railways (estimated) | Underground | Tramways | Omnibuses | Total |
|------------|-------------------------------------|-------------|----------|-----------|-------|
| 1913 . . . | 450                                 | 298         | 812      | 736       | 2,296 |
| 1919 . . . | 505                                 | 480         | 1,064    | 861       | 2,910 |
| 1923 . . . | 488                                 | 367         | 1,001    | 1,214     | 3,070 |
| 1924 . . . | 474                                 | 369         | 983      | 1,485     | 3,311 |

In 1925 a grand total of 3,524,000,000 was reached. The increase in the volume of traffic is out of all proportion to the growth of population. A principal factor in the increase of congestion on the streets is the growth and spread of the travel habit. It has been estimated that whereas in the year 1900 every Londoner, man, woman and child, travelled 158 times a year, that figure had risen in the year 1925 to 460. The burden thus thrown upon the transport agencies is even greater than these figures would indicate, owing to the fact that the "peak" periods of the day are now more compressed. The

hours of industrial workers having been shortened, their travel period now tends to coincide with that of the clerk and warehouseman, with the result that travelling facilities have to be provided for a heavier peak traffic concentrated within a shorter number of hours.

**Remedies.**—The remedies for traffic congestion on the streets are easier to enumerate than to apply. First and foremost all wanton obstructions should be removed; fountains, clock-towers, refuges, obelisks, horse-troughs and such like structures erected in the leisurely days of an earlier century must justify their existence in the light of changed circumstances. Street traders and stalls must be relegated to side streets; slow and heavy vehicles must be prohibited from using, during the busy hours of the day, certain routes in which rapid movement is indispensable; the position of the great markets must be reconsidered in order that the streams of ponderous traffic to which they give rise may not choke all-important adjacent arteries. By extending railway sidings into markets, now served by road, much of the congestion on the latter might be relieved.

**Parallel Routes.**—A useful purpose may be served by the judicious sign-posting of parallel routes, so that inexperienced drivers may be induced to leave the overcrowded roads and make use of less familiar thoroughfares. A glance at the map of our great cities will show how many such alternatives are already available and how many more might be rendered feasible by the demolition of a few buildings which interrupt the continuity of a line of streets. In many instances greater advantage would accrue from the completion of an alternative route by the acquisition of such obstructive buildings than from the customary widening at enormous cost of the principal thoroughfare by the demolition of one entire frontage. Two roads are better than one, seeing that an accident may at any time have the effect of closing a single thoroughfare, however wide. Unavoidable traffic stoppages due to road repairs can be shortened in many cases by the use of quick-setting cements and the introduction of pneumatic tools for breaking up old foundations. In the

busiest thoroughfares repairs should proceed uninterruptedly day and night. Co-ordination between adjoining highway authorities would prevent the annoyance of parallel routes being simultaneously closed for repair. The extreme need of some co-ordinating body for London led to the creation in 1924 of the London and Home Counties Traffic Advisory Committee, which reports to the Minister of Transport upon all matters affecting transit in that populous area.

*Single-way Traffic.*—Narrow streets which are so situated as to form useful lines of communication can often be advantageously utilised as single-way routes, a practice which has been widely adopted in Paris, where no less than 105 streets are reserved for one-way traffic. Obviously the facilities for establishing alternative routes and single-way routes are greatest in cities which have been methodically laid out on a fairly rectangular plan. In cities of haphazard growth more formidable difficulties will arise. The delay inflicted upon traffic at busy cross roads can be eliminated by the enforcement of gyratory movement in the rare cases where space permits, or by the construction of a bridge or tunnel enabling one stream of traffic to pass over the other—a device that is only rendered feasible by a convenient configuration of the ground. The ample dimensions of the “places” of Paris have enabled gyratory movement to be instituted at 19 traffic centres, whereas in London the experiment was tried in Jan. 1926, for the first time, in Aldwych and Parliament Square (see fig. 1) where its success has led to its extension to other traffic centres.

## II. IN THE UNITED STATES

*New York.*—A distinctive aspect is given to the traffic problem of New York by the grouping within a restricted central area (Manhattan) of sky-scrapers, (Woolworth, Singer, Equitable, etc.) accommodating thousands of workers whose movements create congestion of perilous intensity. Somewhat similar conditions prevail in the “Loop” district of Chicago, where nevertheless only some few of the buildings exceed 17 storeys in height but where the day population exceeds 2,500 per ac., as compared with 614 per ac. in the City of London. The difficulties thus created are aggravated by the almost universal ownership of motor-cars in the United States, where in some towns one car is counted for every five inhabitants (men, women and children). Europe can produce nothing comparable with the transit problems presented by the massing within the Woolworth Building in New York of a working population of 14,000 souls—exclusive of visitors. The impossibility of providing stances for motor vehicles within easy walking distance of such a building is likely to militate against the more extended urban use of the automobile. It has been pointed out by Dr. Raymond Unwin that if only one in 10 of the occupants of the Woolworth Building wished to park a car it would be necessary to provide for that purpose exclusively a carriageway 60 ft. wide and three quarters of a mile long.

*Chicago.*—At Chicago, within the “Loop” district, the streets which represent no less than 40% of the ground-space are quite inadequate to carry the present traffic, and of the 60,000 motor-cars owned by the occupants of the “Loop” only 3,500 can find standing-room within the district. Temporary relief is afforded by the large open space set aside for Grant Park, where as many as 25,000 motor-cars have been seen parked at one time.

*Regulations of Traffic.*—The ever-growing demands made upon the police for the marshalling and regulation of street traffic have led to the introduction, in many cities, of mechanical signalling devices designed to reduce the staff and lighten their labours. Among such devices are the lamps now installed at cross roads on some of the Paris boulevards, which, by means of red and green lights, signal traffic to stop on one thoroughfare and proceed on the other, reversing these instructions at regular intervals, so that in each direction the flow of traffic is alternately held up and released. In some instances the change of signals is heralded by the sounding of a bell. In the larger American cities light-towers have been introduced as a means to the more scientific marshalling of traffic. These towers, erected at

convenient points, are regulated from a master control tower, so that the traffic extending for a distance of from three to seven m. can be alternately held up and released, the period of arrest being carefully calculated in proportion to the relative volume of north-south traffic and east-west traffic respectively, so that the heavier stream may have the longer period of flow.

## III. SOME SUGGESTIONS

*Circumferential Roads.*—Whatever efforts may be made to take full advantage of the roads already in use, the vast increase in vehicular traffic will in most of our growing cities call for the provision of additional thoroughfares. While the radial roads may be tolerably adequate it will usually be found that suitable circumferential roads are wanting, save in the case of towns whose fortifications have given place to a ring road. Relief to the congested centre of a city can often be most readily afforded by the building of circular roads which enable traffic to pass round the outskirts. By suitable regulations it should then be possible to limit the passage through the crowded centre to vehicles whose business legitimately requires their presence there. Little hardship is inflicted upon drivers who are relegated to the circular road, seeing that, although their journey may be longer, the time occupied is less, owing to the absence of congestion. As a good example of this type of route may be cited the circular road, 26 m. long, in 1926 approaching completion round the north of London.

*Town Planning.*—For the provision of new relief-roads in areas still undeveloped much can be done by the adoption of town planning procedure which enables the line of route to be laid down several years in advance, with a view to its ultimate construction as and when the land traversed is developed for building purposes.

*Co-ordination.*—At the root of the traffic problem in great centres of population lies the difficulty that the present local government boundaries usually have no relation whatever to the wider traffic region upon which the welfare, the work and the very existence of the city depend. Concerted action for the common good is defeated by the multiplicity and divergent interests of the small administrative units which encircle the city. In the aggregate the resources of the greater community forming the traffic region are amply sufficient to provide the remedies which are admitted to be necessary, but the application of these resources to the desired purpose is impracticable, in the absence of some public body empowered to determine the best means of promoting improvement schemes and to apportion the cost over the traffic region which ultimately benefits. Until this power of apportionment can be exercised there are insurmountable obstacles to the execution of vital improvements in poverty-stricken administrative areas, where local conditions often generate traffic delays reacting injuriously upon the whole traffic region. An authority exercising control over such a traffic region would naturally be charged with the duty of co-ordinating the different traffic agencies and means of transit, so as to eliminate wasteful competition and the congestion to which it gives rise. Certain routes would be reserved for trams or trolley vehicles, others for motor-buses, others for underground railways. The number of vehicles plying on various routes would be restricted to the needs of the travelling public, instead of being dependent upon the varying fortunes of the struggle between rival undertakings. It is indeed questionable how much longer the interests of the citizen can tolerate the use of the public highway as the arena for unrestricted traffic competition.

*Franchises.*—Many great cities have already had to adopt a “franchise” system, under which exclusive privileges are conferred upon particular traffic agencies in return for guaranteed services at prescribed fares. Even if the inconvenience of traffic congestion due to free competition were less marked, the arguments for some form of “franchise” system would still be cogent, owing to the fact that the fresh capital which is urgently required for the modernisation and extension of certain traffic agencies will not be forthcoming unless some security is afforded to those operating the undertaking.

*Railway Electrification.*—The need for additional resources is acutely felt by congested suburban railways constructed in the days of steam traction. Electrification of such lines is often the only means of increasing their carrying capacity and great activity prevails in the application of this remedy. As an instance may be quoted the electrification of the London suburban lines of the Southern Railway, involving the conversion of 650 m. of track, at a cost of nearly £8,000,000. The traffic flow of a railway being governed in large measure by its terminal capacity, the aim must be to enable the largest number of trains to enter and leave the terminal. It has been claimed that thanks to electrification the capacity of terminals can be increased by 150%, so that five trains would run where two ran formerly (see RAILWAYS, ELECTRIFICATION OF).

*Future Developments.*—Casting a prophetic glance forward one can discern certain directions in which the development of our civic, social and industrial life may be fundamentally affected by the pressure of the traffic problem. There is already a tendency towards the creation of self-contained satellite towns of moderate size where the citizen can live within an easy walk of his work and yet within sight of the green fields. The administrative centres of capital cities can be relieved by moving to the open outskirts of towns certain offices and departments which do not require an absolutely central position. As open spaces in central districts become rarer and rarer we may see legislation promoted to safeguard such squares and gardens as have escaped the builder.

*Continuous Use of Offices.*—It is conceivable that the high rental value of office accommodation in the heart of great cities and the increasing closeness of business contact between countries of every latitude may lead to the continuous use of offices throughout the day and night, with the result that the volume of passenger traffic to and from the suburbs would be better distributed. It is perhaps significant that several London restaurants should remain open throughout the 24 hours. A time may indeed be in sight when the problem of transport will be the dominating influence in moulding the life of the citizen in every highly developed industrial community. (H. Mv.)

**TRAINING CAMPS.**—Prior to 1913 the people of the United States, although certain to be involved in the approaching world crisis, had made no military preparation which would enable them to play their appropriate part in the struggle for civilisation. Impelled by an appreciation of this situation, and realising that the interest necessary for properly meeting it could best be built up through the youth of the country, Maj. General Leonard Wood took up in 1913, as chief of staff of the army, with the Secretary of War, Lindley M. Garrison, the project of establishing training camps for duly qualified youths, and obtained his approval. The project was pushed forward by General Wood in the following three years.

*1913 Camps.*—The 1913 camps, known as Students' Military Instruction Camps, were held at Gettysburg, Pa., and Monterey, Cal., and were made up principally of college students. The total number in camps was 244. Those at Gettysburg formed a permanent organisation, which became known as the National Reserve Corps, and had for its purpose the building up of a corps of reserve officers. The results at Gettysburg and Monterey were such that these first camps attracted immediate and favourable recognition, and were the seeds from which sprang the Plattsburg camps. The active co-operation of the universities and high schools was secured through the efforts of General Wood and President Drinker of Lehigh University, who took steps leading to the organisation of an advisory committee consisting of the outstanding university executives in the United States.

*1914 Camps.*—The following year (1914) camps were established at Fort Ethan Allen, Burlington, Vt.; Asheville, N.C.; Ludington, Mich.; and Monterey, California. The total number in the different camps was 667. These aroused a gradually growing interest, reinforced by considerations growing out of the outbreak of the World War, and the Department of War determined that four such camps should be established during

the summer of 1915, at Chickamauga Park, Ga.; Plattsburg N.Y. (three camps); Ludington, Mich.; and at the Presidio, San Francisco, California. The total number of men who passed through the camps during this year was 3,406. The camps were no longer limited to students from colleges and high schools, but were open to men from all walks of life who had the necessary physical qualifications and showed sound qualities of leadership. As Plattsburg was the largest training centre, the camps, wherever held, began to be called "Plattsburg Camps."

*The Army Report.*—Speaking of the training camps, the chief of staff of the army, in his *Annual Report for 1915*, said:

The reports show that the results have fully justified the establishment of these camps . . . Aside from the military instructions given these students and business men, I feel that the interest in preparedness which leads these men not only to give their time to the government but to incur the expense of buying uniforms and paying for transportation to the camps is of great value to the country, and should be encouraged by the War Department. These camps have passed the experimental stage, and there can hardly be any question as to the advisability of continuing them and extending them where the conditions of service of regular troops are such as to permit the department to send troops and instructors to the camps. Men with means probably do not object to paying the necessary funds to get the military training which the government expects to use in case of need. This, however, does not make it right. Men who are not so fortunately fixed financially should be permitted to show their patriotism and interest in preparing the country for war. If these camps are of value, which undoubtedly they are, and are to be continued, certain necessary expenses of the men willing to give their time should be met by the government.

*Developments in 1916.*—In 1916 a series of four camps, each for a month, was held at Plattsburg, N.Y.; a camp of one month's duration for boys at Fort Terry, N.Y.; a series of six camps of two weeks' intensive training at Wadsworth, N.Y., for the police of New York City; and a series of three camps, each for a month, at Oglethorpe, Georgia. Over 16,000 men were passed through the camps. In 1917, applicants for the camps numbered 130,000, and had the United States not gone into the War in the spring well over 100,000 men would have been trained in these volunteer training camps. During the winters of 1915-6 and 1916-7 courses were opened in Boston, New York, Providence, Detroit, Pittsburgh, Philadelphia, and other cities for the instruction and examination of applicants for reserve commissions, and through them were developed a large number of officers who played a vital part in the training of the great War levies.

*War Training Centers.*—When the United States entered the World War these hastily but intensively trained enthusiastic men were invaluable. They furnished the nucleus of civilian officers with which to begin the great work of developing 200,000 officers, and added a valuable and indispensable force to the scanty number of regular officers and national guard officers available for the training of men. In the spring of 1917 the Federal Government took over the whole task and established a series of camps for the training of officers for the War. Under authority of Section 54, National Defence Act, 1916, the Secretary of War directed the establishment of 16 Citizens' Training Camps throughout the United States at the following points: Plattsburg Barracks, N.Y. (two camps); Madison Barracks, N.Y.; Fort Niagara, N.Y.; Fort Myer, Va.; Fort Oglethorpe, Ga.; Fort McPherson, Ga.; Fort Benjamin Harrison, Ind. (two camps); Fort Sheridan, Ill. (two camps); Fort Logan H. Roots, Ark.; Fort Snelling, Minn.; Fort Riley, Kans.; Leon Springs, Tex.; Presidio of San Francisco, California.

*Officers' Training Camps.*—The training camps for officers were ordered to be ready for the reception of reserve officers about May 8, for candidates for commission May 14, and the course of instruction was to begin on May 15 1917. The minimum age for attendance was 20 years and nine months; the maximum age, 44 years. In addition to the foregoing, General Order 119, War Department 1917, established a training camp at Fort Winfield Scott, Cal., for the training of members of the coast artillery section of the Officers' Reserve Corps residing within the territorial limits of the western department, and a similar camp at Fort Monroe, Va., for the balance of the coast artillery reserve corps officers. These training camps began operation on

Sept. 22 1917. 'A medical officers' training camp was also established in 1917 at Camp Greenleaf, Fort Oglethorpe, Georgia. Other camps for officers were established at the headquarters of the various divisions, the courses being essentially the same as those at the former officers' camps. The period allotted for the development of an officer at the government training camps was three months. The work was intensive and hard. It was an attempt, in the rush and confusion of war, to produce officers in the minimum period of time. The purpose was to turn out the largest possible number of platoon leaders and a limited number of company commanders and officers of field grade. The same general plan was carried out at the training camps for officers in the quartermaster corps, medical corps and other staff corps. The courses involved much hard work and were necessarily defective in some particulars, but they served to turn out many tens of thousands of officers with elementary training which was later supplemented by their work with the divisional organisations to which they were assigned.

*Public Support.*—Theodore Roosevelt gave the full support of his great prestige and influence in the upbuilding of the camps, and never lost an opportunity to impress upon the public their importance and to push forward their development. Men too numerous to mention, men who are leaders in every walk of life, co-operated to the limit of their ability in the upbuilding of these camps, and in waking the country to an appreciation of the gravity of the situation and the need of preparation. The camps were a great force in firing the public conscience and rousing the people to a realisation of their obligation to prepare the country for defence and to do their part in the great struggle then threatening the world. (L. Wo.)

**TRANSCAUCASIA** (see 27.172).—The Transcaucasian Socialist Federated Soviet Republic comprises the former states of Azerbaijan, Armenia and Georgia with an area of 195,800 sq. km. or 0.9% of the area of the Soviet Union (U.S.S.R.).

*Area and Population*

| Soviet Republic | Area in<br>sq. versts | Population |
|-----------------|-----------------------|------------|
| Azerbaijan      | 76,447                | 2,125,152  |
| Armenia         | 34,288                | 1,400,000  |
| Georgia         | 57,967                | 1,792,000  |
| Total           | 168,702               | 5,317,152  |

Out of the total population, just over 1,000,000 or about 19% are classified as urban, the remainder being engaged in rural pursuits. The total population represents 4.1% of the population of the U.S.S.R.

*Political History.*—On Sept. 20 1917 a council of Transcaucasian peoples met at Tiflis and declared Transcaucasia to be a Federal Republic within the Russian dominions. The effects of the Bolshevik revolution began to be felt in the following spring; in March a Bolshevik rising took place in Baku and established a Soviet régime, and in April the council declared the complete independence of the Federal Republic. In May it opened peace negotiations with the Germans and Turks, the latter having invaded the country and captured Batoum and Kars.<sup>1</sup> The Federal Council dissolved, however, on May 26; Georgia declaring its complete independence and National Councils of Armenians and Tartars taking over the administration of Armenia (Eriyan) and Azerbaijan. Separate treaties were signed by Georgia with Germany on May 28th and by the three republics with the Turks and Germans on June 4th, which resulted in the "friendly" occupation of Armenia by the Turks and of Georgia by the Germans. In the following month the Bolshevik administration at Baku was overthrown and on Aug. 4th the advance guard of a British force under Maj. Gen. L. C. Dunsterville landed and were soon engaged in defending the town against the Turks (see PERSIAN CAMPAIGNS). On Sept. 14 the British troops evacuated Baku, which was then occupied by the Turks and became the seat of the Azerbaijan Government. The Turks, however,

were compelled to evacuate the whole of Transcaucasia by the terms of the Armistice with the Allies of Oct. 30, and in the middle of Nov., Baku was reoccupied by a British force which administered the district on the collapse of the existing Azerbaijan Government. Just before the close of the year further British forces landed at Batoum to occupy Georgia and Armenia.

During 1919 the three Governments gradually established themselves, under the protection of the British forces, though Armenia opened hostilities in Jan. against Georgia and in Aug. against Azerbaijan. In both cases the disputes (territorial in origin) were settled by British mediation. The British forces evacuated the whole of Transcaucasia except Batoum on Aug. 28 1919. In Jan. 1920, the Supreme Council sitting in Paris accorded *de facto* recognition to the three Governments. On April 27-28 there was a revolution at Baku and the Azerbaijan Govt. was replaced by a Soviet Republic which invited the Russian Soviet forces to occupy the country. Georgia and Armenia, however, retained their independence for a time, and the former signed treaties with the Soviet Governments of Azerbaijan (May 7) and Russia (June 6), a step which Armenia refused to take. On July 7 the British forces evacuated Batoum and handed over the district to the Georgian Govt., whose independence was recognised by Soviet Russia in a second treaty signed in August. On Aug. 10 Armenia was compelled by threat of force to sign a treaty with Soviet Russia, but was shortly afterwards attacked by the Turkish Nationalists and the Soviet Govt. of Azerbaijan, with the connivance and support of Soviet Russia. In the result an Armenian Soviet Govt. was established in Dec., whose independence was recognised in a treaty by Soviet Russia.

On Jan. 27 1921, the Supreme Council sitting in Paris accorded *de jure* recognition to the Menshevik Govt. of Georgia, but on Feb. 12 there was a rising against this Government in the country and a week later the Russian Soviet troops crossed the frontier. Turkish forces then occupied Batoum at the invitation of the Mensheviks, but withdrew on the signature of peace and the proclamation of a Georgian Soviet Republic (March 19). In the following May a treaty of Alliance was signed between the Georgian and Russian Soviet Governments. Meanwhile the three refugee Governments from Georgia, Azerbaijan and Armenia had fled to Paris and there proclaimed a Caucasian Federation, asserting that the respective Soviet Governments did not represent the wills of the three peoples. A revolt against the Armenian Soviet Govt. in the summer was easily suppressed. The three Soviet Govts. regulated their relations with Turkey in a treaty signed at Kars on Oct. 13, the provisions of which followed the lines of the Treaty concluded in Moscow between Russia and Turkey, March 16. On March 12 1922 the three Soviet Govts. signed an agreement establishing the Transcaucasian S.S.S.R. which, though in close alliance with the Russian Soviet Republic, retained a nominal independence until the creation of the Union of Socialist Soviet Republics (July 6 1923) of which it then became a constituent member. (see RUSSIA).

*Natural Resources.*—Transcaucasia contains some of the finest mountain scenery in the world; the vegetation ranges from sub-tropical on the west coast of Georgia to the dry and arid region of Kura, where cultivation is only possible by artificial irrigation, while Armenia is predominantly pastoral. The forest area comprises some 12,000,000 ac. rich in numerous varieties of timber; beech, oak, hornbeam, pine, spruce, fir, are the chief, but the commercially valuable varieties are said to be in the neighbourhood of a hundred. The chief agricultural crop is maize, but wheat and barley are also grown, while rice and cotton are cultivated in the eastern districts. The mulberry tree is also cultivated and there the silk-worm industry is reviving, the output in 1924 being about 35% of 1913, but the raw silk is sent to Moscow for manufacture. Tea planting is steadily increasing, the area planted having risen from 405 ac. before the war to 2,700 ac. in 1924. The plans of the Georgian Government propose a further extension to 16,200 ac. by 1929. The principal mineral deposits are oil (in the neighbourhood of Baku, Azerbaijan *q.v.*),

<sup>1</sup> By the Treaty of Brest-Litovsk (March 3 1918) Russia had ceded to Turkey the districts of Kars, Ardahan and Batoum.

electrons being equal to the atomic number of the element, thus causing the system to be electrically neutral. The ordinary chemical and physical properties which characterise any element are due to its particular configuration of extra-nuclear electrons, and are thus controlled by the nuclear charge.

To bring about a transmutation from one element to another it is therefore fundamentally necessary for the nuclear charge to be increased or decreased by some means, for if this can be brought about the configuration of external electrons will adjust itself to the changed conditions. The experimental difficulties involved in effecting a change of nuclear charge would be expected to be very considerable, and up to the present time the record of definite evidence of the successful achievement of such an alteration—i.e., of artificial transmutation—is not very extensive.

*Spontaneous Transmutations.*—The spontaneous transmutations which we have in the radioactive series of elements are transformations in the direction of decreasing atomic mass, and lead to the attainment of ultimate stability in the direction of decreasing atomic number. It does not however follow that artificial transmutation will necessarily be most easily brought about in the same direction.

*Conditions of Transmutation.*—There is strong evidence that protons (or hydrogen nuclei—positive particles of unit mass and unit charge),  $\alpha$ -particles (or helium nuclei—positive particles of mass 4 and charge 2), and electrons, enter into the nuclei of the atoms of the heavier elements as constituent units. Transmutation would therefore necessarily take place if either a proton, an  $\alpha$ -particle, or an electron, could be caused to enter or leave the nucleus of any atom.

*Experimental Work.*—By bombarding the atoms of various elements with  $\alpha$ -particles, Rutherford and Chadwick, and subsequently Kirsch and Pettersson, have found that from several elements particles are produced which are capable of causing a scintillation on a fluorescent screen placed far beyond the range of the original  $\alpha$ -particles. From experiments on the bending of their paths by a magnetic field, these particles were shown to be protons. After testing in various ways to find out whether they could have originated from hydrogen present as an impurity, either in the elementary form or in combination, it was concluded that these particles must have come from the atoms of the element under test. Nitrogen was one of the first elements for which this effect was found, but many other elements have since been shown to give rise to protons when bombarded by  $\alpha$ -particles. The ejected proton eventually acquires an electron and settles down as an ordinary hydrogen atom. The actual proportion of the impacts which result in disintegration and the production of hydrogen is, of course, extremely small.

*Ejection of Units.*—In these cases we have clear instances of transmutation by the ejection of one of the units of their structure from the nuclei of atoms, the definite evidence of the transmutation being the detection and identification of the ejected portion. With regard to the ultimate condition of the remaining part of the bombarded nucleus, and the fate of the bombarding  $\alpha$ -particles there is no evidence in the case of most of the elements, but with nitrogen a definite investigation of these problems has been made by Blackett, who, by the Wilson cloud condensation method, photographed the tracks of a very large number of  $\alpha$ -particles through nitrogen, and was able to identify several of these tracks as showing the occurrence of a disintegrating impact. In each of these cases only one track other than that due to the projected proton could be found diverging from the point marking the occurrence of the disintegration. From this it was concluded that the bombarding  $\alpha$ -particle was retained by the struck nitrogen nucleus, thereby producing a system of mass 17 and nuclear charge 8, a system which would be an isotope of ordinary oxygen.

The experiments conducted by Blackett could not by their very nature enable a decision to be made as to whether such a system has any permanent stability. Harkins and Ryan, and Akiyama, have on the other hand obtained photographs of  $\alpha$ -ray tracks in air showing collisions resulting in disintegration,

with three branches diverging from the point marking the occurrence of the collision. As the disintegrating atoms in air were presumably nitrogen atoms, these results seem to indicate that even in any one substance the fate of the bombarding  $\alpha$ -particle is different in different disintegrating collisions.

*Further Evidence.*—In addition to the evidence of transmutation of elements resulting from  $\alpha$ -particle bombardment of atoms, we have the evidence brought forward independently by Miethe and Stammreich, and by Nagaoka, of the conversion of mercury into gold, and the evidence recorded by Smits of the production of thallium and mercury from lead. In each case the recorded transmutation is in the direction of decreasing atomic number, but there is no evidence as to whether the changes involve decrease of atomic mass or not. The change from mercury (atomic number 80) into gold (79) might conceivably be effected either by the entry of an electron into, or the removal of a proton from, the nucleus of the mercury atom, and the same alternatives present themselves in regard to the transformation of lead (82) into thallium (81).

Nagaoka, in attempting to bring about the transformation of mercury into gold, held the view, based on a consideration of the resemblance of the non-series spectrum lines of gold and mercury, that in the mercury nucleus a proton existed as a sort of satellite to the main nucleus, which was the same as that of the gold atom, and he designed his experiments with a view to bringing about a powerful disturbance of the nucleus in the hope of ejecting the satellite proton. He passed a discharge in paraffin oil between electrodes of iron and purified mercury with a short spark gap, using an induction coil of 120 cm. spark length. After four hours he succeeded in obtaining evidence of the presence of gold, and confirmed his result by subsequent experiments. Although the experiment was designed to facilitate the ejection of a proton from the mercury nucleus, it would not preclude the possibility of a transmutation being effected by the entry of an electron into the nucleus.

Miethe and Stammreich's experimental arrangement was entirely different, for they obtained traces of gold from mercury vapour lamps in which a heavy current had been passed under a potential difference of only 170 volts. The arrangement employed by Smits was somewhat similar to that of Miethe and Stammreich. It consisted of a quartz lead-vapour lamp of special design run at voltages of less than 100 and with currents up to 100 amperes. Smits records that initially the spectrum showed only one of the mercury lines, namely  $\lambda 2536$ , but that after running the lamp for 10 hours the strongest mercury lines in the visible as well as the ultra-violet region of the spectrum had made their appearance, and that the most characteristic thallium line was also visible. It is difficult to believe that the electric field due to a potential difference of only 100 volts or so across the tube would be strong enough to effect the disruption of an atom and to bring about transmutation by the ejection of a proton, and the alternative possibility of the entry of an electron into the nucleus must be taken into account.

In the case of the transmutation of lead (82) into mercury (80) the change might take place either by the intermediate production of thallium by one of the processes already suggested, and the subsequent conversion of thallium into mercury by one of these processes, or it might occur as a one-stage transformation by the ejection from the lead nucleus of either one doubly charged positive particle (presumably an  $\alpha$ -particle) or two singly charged positive particles (presumably protons) simultaneously. The fact that Smits records stronger evidence of the production of mercury than of the production of thallium seems to argue against the formation of mercury from lead by the intermediate production of thallium in his experiments.

When atoms are bombarded by high speed electrons, it is possible that occasionally an electron penetrates within the K shell of extra-nuclear electrons. If such a penetration does occur the electron will be attracted towards the nucleus and may perhaps be absorbed by it. It is possible that something of this kind occurred in the experiments of Miethe and Stammreich, and of Smits, giving rise to the detected gold and thallium respectively, though it is surprising that the penetration of the K shell of electrons could occur with the small potential differences they employed. If a nucleus were to absorb an electron in the way suggested it is possible that with some nuclei instability would result and disruption occur. This can perhaps be more readily imagined if the nuclei have satellite protons as suggested by Nagaoka in the case of mercury. In the case of an element such as lead, for which several isotopic forms occur, it is conceivable that the close approach of an electron to the nuclei of different isotopes would have different results. That the mercury detected in Smits' experiments could have been produced from the disruption of the nucleus of one of the lead isotopes following instability resulting from the close approach of an electron to the nucleus, must however, be regarded simply as a conjecture. For a discussion of the subject see Sir E. Rutherford, *Electricity and Matter in Phases of Modern Science* (1925).

**TRANSPORT:** see FLYING; INLAND WATER TRANSPORT; MOTOR TRANSPORT.

**TRANSPORTATION:** see URBAN TRANSPORTATION.

**TRANSVAAL** (*see* 27.186), since 1910 a province of the Union of South Africa. Area, 110,450 square miles. Population (1921), 2,087,636, compared with 1,686,212 in 1911 and 1,269,051 in 1904. The white population increased from 297,277 in 1904 to 543,485 in 1921, a reflection chiefly of the development of the gold and coal-mining industries. Half the white population was concentrated on the Rand, where there are six large municipalities besides Johannesburg (*q.v.*), the largest city in South Africa. Brakpan is the centre of the Far East Rand, from which since 1921 the bulk of the gold has been mined. The only other big town is the capital, Pretoria (*q.v.*).

Apart from gold-mining, which maintains its position as the chief industry, there has been a notable increase in the production of coal. Copper has been produced in considerable quantities since 1914, and in 1923 a valuable discovery of platinum was made in the northern Transvaal, though up to 1926 the mines had not reached the producing stage. The Transvaal also maintained its position as a stock-raising country. The cultivation of maize and tobacco largely increased, and (since 1917) cotton has been extensively planted, while manufacturing industries have been developed on the Rand.

As in the other provinces, the bulk of provincial expenditure was on education, the provincial council being noted for its many educational experiments. On the language question from 1912 onward instruction in the lower standards was in "the home language of the child." Primary education is compulsory, and both primary and secondary education is free. Expenditure on education, which in 1915-20 averaged £1,203,000, was £2,508,000 in 1922-3. Expenditure on general administration for the same periods was £69,000 and £106,000. The subsidies from the Union Govt., which averaged £841,000 in 1915-20, were £1,456,000 in 1922-3. An item of revenue peculiar to the Transvaal is a native pass tax—24s. a year—in labour districts, paid by the employer, elsewhere payable by the native. This tax yields from £330,000 to £350,000 per annum. The provincial system of administration is as in the other provinces (*see* CAPE PROVINCE).

The Transvaal presents in its social life many extremes, the conservatism of the back-veld Boer contrasting strongly with the progressive and democratic spirit of the dwellers on the Rand. Both these elements have their counterparts in other provinces, but party feeling was more strongly expressed in the Transvaal than elsewhere, and this led to the introduction of politics into the provincial council. The white workmen on the Rand form the main strength of the Labour party in the Union.

A considerable number of Boers in the western Transvaal took part in the rebellion of 1914, but the influence of Generals Botha and Smuts kept many burghers loyal to the British connection. The disturbances on the Rand in 1913-4 and the revolt of 1922 were not on racial lines, though the majority of the white miners were Dutch-speaking. But feelings were strongly marked in the provincial council, as was shown by agitations against officials because of their nationality or their politics. Thus, after the general election in June 1924, when the Nationalist and Labour parties gained the victory, there was an agitation to remove the administrator, Mr. J. H. Hofmeyr, because he belonged to the South African party, an agitation which General Hertzog, the Prime Minister, refused to heed. Mr. Hofmeyr's predecessors as administrators had been Mr. Johann F. B. Rissik (1910-7) and Mr. A. G. Robertson (1917-24). (*See* SOUTH AFRICA). (F. R. C.)

**TRANSYLVANIA** (*see* 27.210), a province of Rumania, transferred to that country from Hungary by the treaty of Trianon (1920). Its area is 22,312 sq. m.; and the population (Hungarian census of 1910) 2,678,367. The Hungarian census gave 1,472,031 persons of Rumanian, 918,217 of Magyar and 234,085 of German tongue; these figures certainly over-estimate the Magyar population at the expense of the other nations. The Germans are settled in compact and largely urban settlements, mostly in the south; the Magyars in one compact settlement in the east (Székley) and on the western fringe; most of the landowners and officials were Magyar or Magyarised. The Rumanians form the majority of the rural population.

For administrative purposes, Transylvania is divided into 22

districts, each placed under a prefect appointed by the Government in Bucharest. Transylvania and the Banat send 120 deputies and 60 senators to the Parliament at Bucharest. Of these 18 represented the national minorities (1925).

In Oct. 1918 the Rumanians of Transylvania formed a national committee at Oradea-Mare which, invoking the right of self-determination, claimed separation from the Austro-Hungarian Empire and separate representation at the Peace Conference. In Nov. this committee formally demanded from the Hungarian Govt. the surrender of executive powers in the countries inhabited by Rumanians and eventually assumed administrative control throughout Transylvania and the Banat. On Dec. 1 1918 a national congress, meeting at Alba Latia, proclaimed the union of Transylvania and the Banat with Rumania. The Treaty of Trianon (June 4 1920) ratified this arrangement. The German settlements had voted for the union Jan. 21 1919, but the Magyars only accepted it under protest in 1921.

The chief measures since introduced by Rumania consist of universal suffrage and land reform. The large estates were parcelled out, the previous owners retaining a maximum of 300 ac.; over 100,000 peasant families (2,700 of which were Hungarians) received arable land through this measure. Education, which had been greatly neglected under Hungarian rule, made rapid strides. In 1917 there were five secondary and 2,296 primary Rumanian schools; in 1925 there were nearly 100 and 6,157 respectively; there were 2,231 elementary schools for the minorities (1,669 Hungarian, 403 German) and 148 secondary schools (119 Hungarian, 29 German). (G. Bo.)

**TRAWLING:** *see* FISHERIES.

**TREATIES** (*see* 27.229).—The question of the sanctity or renewal of treaties is always a very serious one at the close of a war. But before the World War many great authorities held the opinion, which was expressed by some (*e.g.*, Professor Oppenheim) actually during the War, that the apparent "breaking-up of laws," which takes place in war is usually succeeded by a stronger emphasis upon them when peace is attained.

The sanctity of treaties is a dogma open to several interpretations. For instance, many international jurists, including Bethmann-Hollweg, hold that Germany committed a breach of international law in invading Belgium in defiance of the treaty of 1839. Others, among whom is Sir Ernest Satow, an authority on both the theory and practice of diplomacy, would maintain that Germany by violating Belgium merely gave any other guaranteeing state the right to attack her. In other words, Germany risked her existence but did not specifically break international law. The difference between these two views is that the first relies upon custom, etc., to establish the sanctity of treaties, and the latter upon force. The difficulty of the first view lies in the fact that custom may change. For instance, it was thought to have been established in 1871 that no great Power which had joined with other great Powers in signing a treaty could violate the provisions of that treaty without the consent of the other signatories, *i.e.*, without a European conference. But in 1908 Austria-Hungary violated Article 25 of the Treaty of Berlin (1878) by annexing Bosnia and Hercegovina, and refused the demand for a conference. There can be little doubt that this principle had been abandoned before 1914. The peacemakers of 1919 therefore tried to set up a state of things whereby the sanctity of treaties would be upheld by the general co-operation of all states. President Wilson condensed this aspiration into a single sentence: "What we seek is the rule of law sustained by the organised opinion of mankind."

*League and Regional Guarantees.*—Some treaties which had proved impotent to guard certain countries, as, *e.g.*, those neutralising Belgium and Luxembourg, were abrogated altogether (*cf.* Articles 31, 40-1 of the German, Article 83-4 of the Austrian and Articles 67-8 of the Hungarian Treaties). The League of Nations Covenant, however, attempted to give a general guarantee to all the members of the League in respect of their territorial integrity and independence. This general guarantee, embodied in Article 10 of the Covenant (*q.v.*), has, on the whole, been rather watered down in its interpretation. It

has, in fact, been succeeded by a system of special or regional guarantees. Thus in the Treaty of Locarno (signed Dec. 1 1925), the demilitarisation of the Rhineland, enacted by the Treaty of Versailles, Articles 42-44, was guaranteed by France, Great Britain, Germany and Italy. This guarantee becomes effective on the admission of Germany to the League of Nations. In case of need Great Britain guarantees France against the unprovoked attack of Germany, and *vice versa*. Similar regional guarantees are given by France to Poland and to Czechoslovakia. The "Little Entente Treaties" (of which the first was signed Aug. 4 1920) constitute a system of regional and special guarantees between Czechoslovakia, the Serb-Croat-Slovene kingdom and Rumania to preserve the territorial limits laid down in the treaties of St. Germain, Trianon and Neuilly (see *LITTLE ENTENTE*). Similarly it was recognised in Article 26 of the Covenant that the Monroe Doctrine was "a regional understanding," which meant a practical admission by the principal Powers that the United States guaranteed other states on both American continents against the aggression of non-American neighbours.

There can be no doubt that many smaller states now enjoy greater advantages under the Covenant and special and local guarantees than did the neutralised states of the 19th century. The Covenant was successfully invoked by Great Britain on behalf of Albania against the Serb-Croat-Slovene kingdom in 1921, and by Greece against Italy in the matter of Corfu in 1923. Also the inclusion of Germany in the League will in itself mean a strengthening of League guarantees.

**Compulsory Arbitration.**—It is a singular and interesting fact that many smaller Powers (e.g., the Scandinavian kingdoms, the Netherlands and China) have signed the compulsory jurisdiction clause in the protocol establishing the Permanent Court of International Justice. If both litigating Powers have signed the compulsory clause a peaceful settlement can be imposed by the court. There can be no doubt that such smaller Powers as cannot depend on the guaranteed protection of larger ones feel that they are safest in this way. And it is an interesting fact that Denmark is the first state in Europe since the War to propose the reduction of her armed forces to the level of mere police, and to trust to the justice and opinion of the world for support in time of need.

If it continues, the Permanent Court will in time create a standard of international justice which it can impose upon all those who have signed the compulsory clause. Were it possible, or certain, that the principal Powers would also sign the compulsory clause the peace of the world could be reasonably assured.

**Abrogation or Renewal of Treaties after War.**—Highly technical points are raised by this question which, though less generally interesting than those already mentioned, are none the less of some importance for the future of diplomacy. Treaties are of two kinds, bilateral between two states, multilateral between several states. All treaties between the contending parties cease on the outbreak of war. It is clear that in the case of bilateral treaties when State A can force State B to sign a treaty of peace after the war, A can renew or refuse to renew with B all the pre-war treaties that she chooses. Germany did not question this right in bilateral treaties. In the case of multilateral treaties the Allies claimed the right to refuse permission to Germany and to the enemy Powers to keep in force treaties with states not actually then engaged in the War, as, e.g., Soviet Russia, or with neutrals who had not been in the War at all though they had severed diplomatic relations with Germany, as, e.g., Peru and Ecuador. In reply to the German protests, the Allies maintained and inserted in the German and other treaties their right to "reapply" all "multilateral treaties which seemed to them to be compatible with the new conditions arising out of the War," and "to indicate which of these treaties with Germany they intend to revive or allow to be revived." The Allies particularly insisted on making Germany grant for limited periods to the Allies themselves or to some of them certain terms already granted to her friends or neutrals. But they did not demand that Germany should be prevented from negotiating new instruments with

states other than the Allies after certain limited periods had passed, e.g., Article 268, of German Treaty. Nor did Germany fail to avail herself of her power. After having been compelled to abrogate the treaties of Brest-Litovsk with Soviet Russia, she negotiated the Treaty of Rapallo with them on April 16 1922. This step evoked much protest from the Allies, and it was contended that Germany had not the right to do it.

The use of power by the victor to enforce on his defeated antagonist the abrogation of treaties with neutrals is not in itself desirable; but it does not appear, on the whole, that such power, even if abused at the moment of victory, is likely to be abused for very long. The special grievances or difficulties thus created by any such abuses in 1919 will be well compensated for if the settlement of Europe has in fact brought a greater sense of security and permanence, whether through the agency of the League, of regional guarantee or of the Court of International Justice. (See also *COMMERCIAL TREATIES*.)

**BIBLIOGRAPHY.**—L. Oppenheim, *International Law*, 3rd ed., 2 vol. (1920); Sir E. M. Satow, *Diplomatic Practice*, 2nd ed., 2 vol. (1922). Each of the Peace treaties of 1919 contains a section headed "Treaties." The passages on Treaties in the *German Observations* on the draft Treaty and the *Allied Reply* are quoted in H. W. V. Temperley, ed. *History of the Peace Conference of Paris*, 6 vol. (Institute of International Affairs, 1920), 322-6, and these are authoritative expositions of the rival points of view.

(H. W. V. T.)

**TREE, SIR HERBERT BEERBOHM** (1853-1917), British actor and manager (see 27.234), died in London July 2 1917. He published a volume of *Thoughts and Afterthoughts* (1913) and other occasional papers. See Max Beerbohm, *Herbert Beerbohm Tree: Some Memories of Him* (1920).

**TRENCH, FREDERICK HERBERT** (1865-1923), British poet and playwright, was born at Avoncore, Co. Cork, Nov. 12 1865. Educated at Haileybury and Keble College, Oxford, he was elected a fellow of All Souls' College, and from 1891-1908 was an examiner in the Board of Education. This appointment he gave up in 1908 in order to devote himself to literary work. In 1908 he became director of the Haymarket Theatre, London, where he staged *King Lear* and Maeterlinck's *Blue Bird*. His first volume of poems, *Deirdre Wedded*, appeared in 1901. It was followed by further poems, notably "Apollo and the Seaman," included in *New Poems* (1907), and *Lyrics and Narrative Poems* (1911). Among his later publications were an *Ode from Italy in Time of War* (1915); *Poems: with Fables in Prose* (1918); and a poetic play *Napoleon* (1919), which was produced in London by the Stage Society in 1919. He died on June 11 1923. His collected works, edited by H. Williams, were published in 1924, and a volume of selected poems in the same year. See Abel Chevalley, *Herbert Trench: Notice sur sa Vie et ses Oeuvres* (Paris, 1925).

**TRENCHARD, SIR HUGH MONTAGUE** (1873- ), British air marshal, was born Feb. 3 1873. Commissioned in the Royal Scots Fusiliers in 1893, he served in the South African War with the Imperial Yeomanry and the Canadian Scouts. From 1903 to 1910 he served in West Africa. In 1912 he qualified as an air pilot and became an instructor at the Central Flying School at Upavon, where he was appointed assistant commandant the following year. On the outbreak of the World War Trenchard assumed charge at Farnborough, but before the end of 1914 was summoned to France, and became head of the military wing of the Royal Flying Corps. His strong personality, foresight and power of command made his name a household word in France, and with the expansion of the air service he rose from major to major-general in little over a year. After the formation of the Royal Air Force he became, in March 1918, chief of the air staff. This position he resigned a month later, owing to disagreement with the first Air Minister, Lord Rothermere. But a few weeks later he received command of the newly formed Independent Air Force, whose mission was to raid Germany, a post that gave scope to his gift for inspiring men and to his development of the strategical rôle of aircraft. In the same year he was created K.C.B.; and in 1919 was again appointed chief of the air staff and received a baronetcy. In 1922 he was promoted air chief marshal.

**TRENT**, England (see 27.250).—A scheme of improvement of navigation between Nottingham and Newark has been proceeding on the river Trent for some years, and aims at encouraging industrial development. The river is to be regulated by locks so that barges of 120 tons will be able to come up to Nottingham. Locks, 190 ft. long and 30 ft. wide, were in course of construction in 1925 at Stoke Bardolph, Hazleford and Gunthorpe, and the last was completed in September.

**TRENTINO**: see TIROL.

**TRENTON**, N.J., U.S.A. (see 27.251), grew to a population of 119,289 in 1920, of whom 30,168 were foreign born; and to 132,020 in 1925 (census bureau estimate). Its factories produced goods valued at \$49,115,000 in 1909; \$122,478,000 in 1919; and almost as much (\$116,622,782) in 1923, after some decrease in the period of depression. It maintained its leadership in the production of pottery, wire and wire rope, structural steel, and linoleum, and ranked second in the manufacture of automobile tires and other rubber goods. The public school system contained 31 schools by 1925, with 698 teachers and an enrolment of over 20,000 pupils. The Board of Health paid particular attention to measures for promoting the health of children, both in the public and in the parochial schools. Three municipal markets were established in 1920. Docks, wharves and warehouses on the Delaware river were owned by the city. A modern sewage disposal plant was under construction in 1925. In 1911 a commission form of government was adopted.

**TREVELYAN, GEORGE MACAULAY** (1876– ), British historian, was born Feb. 16 1876, the third son of Sir. G. O. Trevelyan (see 27.255). Educated at Harrow and Trinity College, Cambridge, he devoted himself to historical research and became an authority on certain phases of Italian history. In 1904 he married Janet, daughter of Mrs. Humphrey Ward.

Trevelyan's works include *Garibaldi's Defence of the Roman Republic* (1907); *England in the Age of Wycliffe* (1909); *Garibaldi and the Thousand* (1909); *Garibaldi and the Making of Italy* (1911); *Manin and the Venetian Revolution of 1848* (1923); *The Life of John Bright* (1913, new ed. 1925); *History of England* (1926).

**TREVES, CLAUDIO** (1872– ), Italian politician, was born in Turin of a Jewish family. He graduated in law and at an early age became a Socialist. He first edited *Il Tempo* of Milan, and when that paper came to an end he joined the staff of *Avanti!*, the official organ of the Socialist party, which he afterwards edited. But he soon resigned, owing to disagreements with the general tendencies of the paper, and subsequently limited his journalistic activities to writing articles in Turati's *La Critica sociale*. He entered Parliament in 1906 as member for Milan, and was re-elected at all subsequent elections, being returned as a Unitarian Socialist at the 1924 elections. In Socialism he represents the orthodox Marxian view. When the split over the reformist tendency occurred at the Reggio Emilia congress in 1912, Treves remained with the majority, but he also held out a hand to the secessionists (Bissolati, Bonomi, etc.). During the World War he adopted an uncompromising non-interventionist attitude. After the Fascist advent to power he ceased to play a prominent part in politics, but he continued to edit *Giustizia*, the official organ of his party.

**TREVES, SIR FREDERICK** (1853–1923), British surgeon, was born at Dorchester Feb. 15 1853, and was educated at Merchant Taylor's School, London, and the London Hospital, where he became surgical registrar. In 1881 he was appointed as professor of pathology and in 1885 as professor of anatomy at the Royal College of Surgeons, subsequently going into private practice. He served as consulting surgeon during the South African War in 1900, and was made surgeon extraordinary to Queen Victoria in that year, and surgeon to King Edward VII. in 1901. He will be particularly remembered for his skill in operating on King Edward VII. when he fell suddenly ill in June 1902. He was created K.C.V.O. in 1901 and a baronet in 1902, and later serjeant surgeon to King George and surgeon in ordinary to Queen Alexandra. During the World War he assisted in the founding of the British Red Cross. His work on the intestinal canals of man and mammals was based on hundreds of original

dissections, and corrected many popular misconceptions. He died at Lausanne on Dec. 7 1923.

His publications include several surgical and medical books, of which *Surgical Applied Anatomy* (1883) is well known, and various treatises on intestinal obstruction, peritonitis and appendicitis, as well as a number of more popular books such as *The Tales of a Field Hospital* (1900), *The Riviera of the Corniche Road* (1921), *The Lake of Geneva* (1922), and *The Elephant Man and Other Reminiscences* (1923).

**TRIANON, TREATY OF**.—The treaty of peace between the Allied and Associated Powers and Hungary was signed at the Trianon on June 4 1920. Owing to the outbreak of Béla Kun's revolution in Hungary, the delegates of that nation were not summoned to the Peace Conference till Nov. 1919. Previous to that date, however, on June 13 1919 the Supreme Council had decided upon the new frontiers of Rumania and Czechoslovakia and had published them. The Hungarian Govt. received the treaty in Jan. 1920 and on June 4 it was signed at Trianon. It actually came into force on July 26 1921.

*General Observations*.—Though the separation of Hungary from Austria and its complete independence are recognised, the details of the Hungarian Treaty otherwise are very closely akin to those of the Austrian. The most important difference is that, while the treaty of St. Germain is signed with the republic of Austria, that of Trianon is signed with Hungary, or with "the national Government of Hungary," a phrase permitting her to be regarded as a Government where the monarchy is temporarily in suspense. Though Charles never abdicated the kingship of Hungary and there is no provision in the treaty for his deposition or for that of any Habsburg, he was formally deposed by a law passed by the Hungarian Assembly (after his attempted Putsch Oct. 1921) at the insistence of the Allies. (See HABSBURG.) On her admission to the League of Nations in 1922 Hungary submitted to the League a document pledging herself not to restore the Habsburgs without the consent of the Allies, and confirming the undertaking to the Conference of Ambassadors of Nov. 10 1921. It may therefore be said that, while an international understanding has been given by Hungary, prohibiting the election of a Habsburg to the Hungarian throne, there is no international obligation to prevent any other individual from being elected king.

*Territorial Clauses*.—The territorial clauses of the Hungarian Treaty reduce her to a population of 7,500,000 (1910 census), of whom 6,250,000 are Hungarians (Magyars); 500,000 are Germans, 500,000 are Jews, 230,000 are Slavs and Slovaks and 50,000 are Rumanians. Fiume was ceded to the principal Allies by article 53 and, after being erected into a free city, was eventually annexed by Italy (1924). Hungary has lost to other nations over 3,000,000 Magyars; of whom 1,500,000 go to Rumania, nearly 1,000,000 to Czechoslovakia and 500,000 to Yugoslavia. These losses have been much bewailed by the Magyars on the ground of self-determination, but their complaints are not wholly sound. Much of the Magyar population lost (as e.g., the Székler area) consists of Magyar islands isolated amid a sea of Slavs or Rumanians. The Pécs area, with its valuable coal mines, has been returned and a line drawn in this area so as to give Hungary a defensible frontier. The chief offence against nationality is on the eastern border of Hungary, where the line is so drawn as to give to Rumania the three Magyar towns of Satul-Mare (Szatmár), Oradea-Mare (Nagyvárad) and Arad and the surrounding Magyar zone. But this concession was made primarily for economic reasons. Without the railway line connecting these three cities from north to south there would be no connection between north and south Transylvania.

Had the Hungarian Govt. possessed the intervening strip, it would certainly have made difficulties as to the cheap and easy transport of food from south to north. On the whole, however, whether we consider Rumania or the Serb Croat-Slovene kingdom, we must admit that both got much territory at Hungary's expense, though neither of them got as much as they wanted and demanded. The Hungarians, with complete indifference to the claims of nationality, have always asserted that they have a

right to the whole original kingdom of Hungary, including the Rumanians, Slovaks, Italians, Serbs, Croats and Germans, of which the Magyar population formed little more than half. It is entirely true to say that the Allies, in making the Treaty, showed much more respect for nationality than Hungary has ever done.

Articles 36-78 deal with the details of ceding territory to Italy, Czechoslovakia and Yugoslavia, and are similar to the corresponding section in the Austrian Treaty. Hungary is less affected by interests outside Europe than Austria, but is, none the less, compelled to cede all rights in capitulations, concessions, etc., in China, Siam, Egypt, etc.

*Part V.*—The military, naval and air clauses are almost exactly similar to those of the Austrian Treaty, except that Hungary is allowed an army of 35,000 instead of Austria's 30,000. *Part VI.*, *Prisoners of War and Graves*, and *Part VII.*, *Penalties*, are the same as in the Austrian Treaty. (See ST. GERMAIN, TREATY OF.)

*Part VIII.*—*Reparation.*—This section is verbally almost identical with the Austrian section, and both are a close imitation of the German. For various reasons it was not possible to fix the exact amount of reparation. But Hungary was forced to surrender all rights to her merchant ships on "the ton for ton, class for class basis," and her reparations in kind were to be fixed in three months by the Reparation Commission, which was to deliver cattle to Italy, to Rumania, and to the Serb-Croat-Slovene kingdom (Annex. iv. to Part viii.). As parts of Hungary had already been amply sacked by Rumanian soldiers in Aug. 1920, this did not leave them much livestock in hand.

*Financial and Economic Clauses.*—Articles 180-199 are mainly concerned with liquidating the Austro-Hungarian National Bank, thus separating the last link with Austria. *Part X.*, the economic clauses, calls for no special remark, nor does *Part XI.*, *Aerial Navigation*. The economic clauses are the same as the Austrian, the latter like that of both German and Austrian Treaties. *Part XII.*, ports, waterways and railways, is mainly concerned with the regulation of the Danube, for which a Statute was eventually drawn up. As in the case of the Austrian Treaty (Article 311), the Hungarian in Article 294 provides for the free access of Hungary to the Adriatic, though practically nothing has been done to secure it. *Part XIII.*, labour, is the same in all treaties and *Part XIV.*, miscellaneous provisions, calls for no remark.

*Summary.*—In the Hungarian Treaty, as in all others, the war criminals and reparation sections proved impossible of execution. Indeed, it is a great misfortune that these clauses of the Hungarian Treaty were modelled so closely on those of the Austrian and German. In the result, Hungary, being an agricultural country, has proved much more elastic in her recovery than Austria and her economic and financial situation are both sound. It has not proved true, as was averred by her statesmen at the time, that the loss of so much territory and population would cripple her. She retains areas of great agricultural, and some mineral, wealth.

Her conduct is, however, open to suspicion. On her admission to the League in 1922 the military experts stated that her army was above the limit of 35,000 men, and there was an extraordinary forgery of French francs in 1926 in which a prince, a bishop, the Budapest chief of police and possibly higher officials, were implicated. The real cause of discontent is the refusal of the Magyar irredentists to accept the inevitable and their incessant pressure upon the Government. The prospect is not a good one in the political sense, but the presence on her borders of three hostile nations, each formidably armed, is probably sufficient to keep the peace for some years. That the present treaty will ever be sincerely accepted by the present governing class in Hungary no one acquainted with their mentality believes to be possible. But their energy and their resources are quite sufficient to keep the country prosperous, if they abstain from rash political projects.

**TRIESTE**, Italy (see 27.269), a centre of Italian patriotism under Austrian rule, was ceded by Austria to Italy under the

treaty of St. Germain in 1918. Italian, the official language, is generally spoken. With a population of 238,655 in 1921, Trieste is the eighth city of Italy, and the chief port of the Adriatic Harbour improvements were in hand in 1925. The Austrian-Lloyd Steam Navigation Company, which for many years has had its headquarters at Trieste, is now the Lloyd-Triestino Company. There are dockyards and an arsenal. The inland republic of Czechoslovakia has been granted rights in the use of the port. A university was opened in 1924.

**TRINIDAD:** see WEST INDIES, BRITISH.

**TRIPOLI** (see 27.291).—In 1925 the population of this seaport was estimated at 60,000. Since 1912 it has been the capital of the Italian colony of Tripolitania (*q.v.*) which is also commonly known as Tripoli. In a looser sense Tripoli includes, in addition, Cyrenaica (*q.v.*). Considerable improvements have been made in the city and harbour by the Italians. The minimum depth of water at the entrance to the port is 24 ft.; at the pier quays 20 to 24 feet. In April 1926 Signor Mussolini visited the town, this being the first occasion upon which a Prime Minister of Italy had set foot in an Italian colony. See A. Fantoli, *Piccola Guida della Tripolitania* (Tripoli, 1925).

**TRIPOLITANIA**, an Italian colony in North Africa (see 27.288), has an area approximately of 300,000 sq. m., mostly desert. The natives numbered, according to a 1925 estimate, between 600,000 and 700,000. European population (1921) 20,716, of whom 18,093 were Italian. The chief towns, all on the coast, are Tripoli (*q.v.*), the capital; Misurata, 14,000 inhabitants; and Homs (see Khoms) 4,000.

*History.*—The vilayet of Tripoli (Tripolitania), together with that of Benghazi (Cyrenaica), passed from Ottoman to Italian rule as a result of the Italo-Turkish war of 1911-2. The Italians at the end of 1912 held only the coast region, and they met with considerable opposition from the natives (Berbers and Arabs) in their occupation of the interior. Their most redoubtable opponent was the Berber chieftain Suleiman el Baruni, who set up an independent kingdom in the Nefusa hills, but was beaten by the end of 1913 and fled to Europe. By Aug. 1914 every place of importance in the vilayet was in Italian hands. Meanwhile in the coast districts the Italians had begun with great energy a big programme of public works, while towards the Arabs and Berbers they adopted a policy of confidence and trust.

Unfortunately, in the adjoining vilayet of Cyrenaica the War continued, the Turks having incited the Senussites to continue the struggle (see SENUSSI). In Sept. 1914 the Fezzani, many of whom adhered to the Senussi sect, rose in revolt. Turkish, German and Senussi propaganda was very active throughout Tripolitania, and the declaration of war by Italy upon Austria (May 28 1915) was the signal for a general rising. There had already been serious fighting with the rebels, and in one engagement the Libyan auxiliaries of the Italians had gone over to the enemy on the field of battle. In view of the situation in Europe the Italians now abandoned the whole country with the exception of the seaports of Tripoli and Homs (Khoms). Another seaport, Zuwara, was reoccupied in Aug. 1916. Meanwhile a brother of the Senussi chief ruled in Fezzan; Suleiman el Baruni reappeared (Sept. 1916) with a firman from the Sultan of Turkey appointing him Governor-General of the vilayets of Tripoli, Tunis and Algiers; Ramadhan el Shtewi, another powerful chieftain, established a so-called Republic of Tripoli and ruled at Misurata, which place became a German submarine base. All through 1917 el Baruni harassed the Italians, but failed to fulfil his boast to drive them into the sea. There was in fact little cohesion and much jealousy among the opponents of the Italians. The Turks sent Prince Osman Fuad to Misurata in April 1918 with instructions to compose the quarrels among the tribes, a task in which he did not succeed. Moreover, the Senussi were now divided, one section, which in the end gained the mastery, having as early as April 1917 come to terms with the Italians—a fact of more importance, however, to Cyrenaica than Tripolitania.

Such was the state of chaos in the country at the end of the World War, and the Italians were then in no mood to undertake

the reconquest of Tripolitania by force. A plan was formed to govern through native chiefs, to whom were to be attached political officers. Negotiations entered into with El Baruni, El Shtewi and other chiefs led to their acknowledgment of Italian rule, and a royal decree of June 1919 gave the country "complete local citizenship" with an elective assembly styled a parliament. The chiefs cared little for such an assembly. They were more concerned in consolidating their own authority and did not scruple to flout that of Italy. There was little real improvement in the situation until Signor Giuseppe Volpi became governor in Aug. 1921.

Under his direction a campaign, which began in Jan. 1922 with the reoccupation of Misurata, was conducted to a successful issue by the end of 1923. Thereafter, by wise and conciliatory measures and by a bold policy of economic reconstruction, Signor Volpi restored order and a degree of prosperity to the greater part of the country, though Fezzan was still troubled by rival factions. In the latter part of his governorship Signor Volpi had the full support of the Fascist Government. For his services he was created Count Volpi of Misurata, and on resigning his post in July 1925 he became Minister of Finance in the Italian Cabinet. His successor as governor was General de Bonis.

**Economic Conditions.**—Owing to the disturbed state of the country little progress had been made up to 1926 in economic development, which depends for marked progress largely on the construction of costly irrigation works. The Italians, however, planted very large numbers of olive, orange, vine and other trees, and began the afforestation of the dunes. Since 1918 Italian immigrants have taken up a number of land concessions and have made fair progress. The Government has built a railway along the coast westward from Tripoli to Zuwara (75 m.) and begun a line eastward to Homs. Another railway (31 m.) runs inland from Tripoli to El 'Aziziya. The chief exports are tunny fish and sponges, henna, esparto grass, wool, dates and salt; the chief imports, foodstuffs and textiles. Trade is mainly with Italy, Malta, Egypt, Greece and Great Britain, and revenue is largely derived from import duties, which give preference to Italian products. According to a British consular report, the value of imports, in 1922 was, in sterling £985,000, while that of exports was only £145,000. The colony has been a considerable burden to the Italian Treasury, largely through military expenditure. The military establishment in 1924-5 was some 17,000 men, of whom 4,800 were Italians. In that year military expenditure was 112,300,000 lire, compared with 34,470,000 lire spent on civil administration.

**TROELSTRA, PIETER JELLES** (1860- ), Dutch politician, was born at Leeuwarden and educated for the legal profession at the University of Groningen, but early abandoned it for politics and journalism. He adopted socialist opinions, but becoming dissatisfied with the leadership of Mr. Domela Nieuwenhuis, under whom Dutch Socialism had assumed an extremist complexion bordering on anarchism, he founded the Social Democratic Labour party in 1894. The new party prospered in the country and in the States-General, and for many years Dr. Troelstra was the acknowledged leader of the Socialist movement in the Netherlands. At the elections of 1918, as a result of the introduction of universal suffrage, the Social Democrats made important gains, and under the influence of the German revolution Dr. Troelstra in a remarkable speech in the Chamber called upon the Government to resign with a view to the formation of a Socialist state. His party, however, refused to support him and the attempted *coup d'état* failed (see NETHERLANDS). Thenceforward Dr. Troelstra's influence steadily declined. In 1925, owing to failing health, he retired from political life.

**TROELTSCH, ERNST** (1865-1923), German philosopher and theologian was born at Augsburg on Feb. 17 1865 and studied at Erlangen, Göttingen and Berlin. He began his teaching career at Göttingen, and thereafter became professor first at Bonn, and then at Heidelberg and Berlin (1915). In 1919 he became a member of the Prussian National Assembly and parliamentary secretary of state in the Prussian Ministry of Worship and Instruction. For some time in 1921 he was a member of the Imperial Government. He died in Berlin on Feb. 1 1923.

Troeltsch was a contributor to the *Theologisches Rundschau*, the *Zeitschrift für Theologie und Kirche*, the *Theologische Jahresberichte*, the *Preussische Jahrbücher*, etc. Among his many works may be mentioned *Die Bedeutung des Protestantismus für die Entstehung der modernen Kultur* (1906, 1924); *Trennung von Staat und Kirche, Soziallehren der christlichen Kirchen und Gruppen* (1919); *Naturrecht und Humanität in der Weltpolitik* (1923).

**TRONDHJEM**, Norway (see 27.305), has grown considerably, and had a population of 55,030 in 1920. A garden suburb has been laid out at Lillegaarden, and costly harbour works have been undertaken. Since 1921 Trondhjem has been connected with Oslo by the Dovre railway.

**TROPICAL MEDICINE.**—As medicine advances from the status of an art to that of a science, so do the bounds which demarcate tropical medicine become more faint. Few major diseases are restricted to the lower latitudes, and tropical medicine, as here considered, embraces all those maladies which, for some reason, prevail especially in the tropics, though not necessarily limited thereto. Some diseases lightly regarded to-day as essentially tropical are merely commensurate with a primitive stage of civilisation, and consequent unhygienic conditions. Bubonic plague smouldered in England for centuries, every few years flaring up to epidemic degree, and ceased as an endemic infection only about 1679. Cholera was common enough in John Wesley's day to demand a paragraph in his little volume on household remedies. The Londoner of Charles II.'s time could enjoy a jest in *Hudibras* unintelligible to anyone not familiar with the stages of a malaria paroxysm. These Captains of the Men of Death, in Bunyan's phrase, no longer menace Britain, but, with many others, they still confront the increasing multitude who follow their avocations beyond the seas.

The present stimulus to the special study of tropical medicine comes from the spread of commerce and empire, from causes far back in history and from the ever-growing complexity of modern economic conditions.

#### SPECIAL PROBLEMS OF TROPICAL MEDICINE

Liability to contract disease in the tropics is not due in the main to inherent change in the individual, but to circumstances generally favouring a luxuriance of animal life. The causative organisms of some diseases, e.g., malaria and yellow fever, depend for their propagation on insects most numerous and active in tropical conditions; warmth and humidity are essential for the development of hookworm larvae in the soil; and in such surroundings bacterial life in general flourishes most abundantly. Though exceptions to these rules spring to the mind—typhus fever, a louse-borne disease, reaches its maximum range under cold weather conditions, and the factors governing the transmission of common colds and coughs determine the spread of pneumonic plague. The newcomer to the tropics is faced by all these potential dangers, with risks of infection usually intensified an hundred-fold by native standards of sanitation.

Preventive medicine has done him one great disservice. Born in pre-hygiene times, he would almost certainly have acquired a natural immunity to a variety of diseases which nowadays in his own country he escapes, but to which the native, surviving childhood, is relatively immune. This resistance to disease, previously believed a racial characteristic, is now generally considered a personal immunity gained by the individual during early life. As regards this aspect of malaria in natives, Christopherson has shown that in hyper-endemic areas children pass through a period of acute infestation lasting for about two years. During this time manifestations of the disease are practically continuous. A stage

of immune infestation is then reached which lasts through childhood into adult life. Whatever the nature of the immunity it is sufficient to enable adults, under conditions that lead to intense infection in the child, to live infected but without suffering appreciably from sickness due to malaria.

The Briton, beyond most others, does not lightly resign his national prejudices and customs, and for years a red tunic and a tight leathern stock were thought suitable wear for the plains of India. So to-day the sojourner in the tropics may complicate the problems of tropical medicine, already sufficiently involved, by an unwillingness to adapt his regimen and habits to new surroundings. Therefore, physiological changes, including alterations in the functioning of the endocrine glands, may result, with a consequent train of morbid symptoms. Native customs and modes of life evolved by the empiricism of years, may repay study. A temporary adoption of the Indian fashion of wearing the shirt outside the trousers has in practise averted the threatened onset of heat stroke. The early inhabitants of Northern Africa cooled their houses by structural devices which modern architects might copy and adapt to the needs of European residents in hot climates. Even the adobe houses of the Mexican natives are designed on sounder principles than the corrugated iron furnaces occupied by white settlers in parts of the tropic zone. Wise in their generation, the Conquistadors did not disdain to learn from the aborigines of the New World, and we are the richer in possessing cincona and ipecacuanha as the result.

#### METHODS OF TROPICAL MEDICINE

Accurate diagnosis is essential to the correct treatment of any disease; this is no new knowledge—"as sayeth the prince of physic Avicenna: 'How shouldest thou hele a sore and not yknow the cause?'" The aim of modern medicine is to prevent rather than to cure, and in like manner a close study of causation is a requisite preliminary to wise and successful prevention. Therefore a basic knowledge of bacteriology, entomology and other branches of medical parasitology is a necessary part of the training prescribed for students of tropical medicine. Not every species of *Anopheles* can be infected with malaria, nor are the breeding habits of all the malaria-carrying anophelines the same. A system of drainage which eradicates malaria in one locality may have no effect in another, and actually may intensify the disease in a third. Slight changes in the chemical reactions of water may prevent mosquito breeding, a discovery likely to have far-reaching results in malaria prevention. And thus the importance of these ancillary sciences to tropical medicine becomes more obvious every day.

Further, statistical data, when investigated and scrutinised by exact methods and correlated with clinical observations, may yield valuable information regarding the nature and origin of disease. If a malady is found to be periodic, the climatic and physical changes associated with the rise and fall of the infection may indicate the causal agents, and when their identity is established effective measures may be taken against them. Rogers' researches show that cholera begins to spread only when the degree of atmospheric humidity has reached a certain figure; in consequence, the possible commencement of an epidemic can be foreseen and appropriate prophylactic measures undertaken in advance. Already tropical research has achieved great triumphs, and when the true economy of preventive medicine is realised more fully in tropical administration, the return in the form of increased efficiency will multiply accordingly.

#### RESULTS

Before the last decade of the 19th century, the agent responsible for the spread of malaria (*q.v.*) was unknown. No eye had seen the bacillus of plague; and fleas were thought merely unpleasant creatures, rather less scandalous than lice. Yellow fever mosquitoes bespotted themselves unheeded, except in so far as they might disturb an afternoon's siesta. But when Patrick Manson argued that some biting insect serves as intervenient host for the nematode parasite of man, *Filaria bancrofti*, and turned his theory into proven fact, he stood like Cortez on a peak

in Darien, viewing a new world. Following on Manson's example and advice, and faced by difficulties which would have disheartened most, Ross carried out his laborious researches and finally *Anopheles* was incriminated as the vector of malaria.

In the old yellow fever (*q.v.*) days, a king's ship, the "Tiger" cruised off Barbados, and out of a complement of 220, buried 600 men dead of yellow fever within two years; the commander, as he reported, "still pressing men out of the merchant ships that came in, to recruit his number in the room of those that died daily." The heroic work of Reed and his collaborators proved that this infection is transmitted through the bite of a mosquito, *Aedes argenteus* (*Stegomyia fasciata*), and Noguchi's discovery of the causative micro-organism has confirmed their work. Fortunately the peculiar breeding habits of the insect vector render it relatively easy to control, and in the West Indies to-day yellow fever is little more dreaded than in England.

Ankylostomiasis (hookworm) (*q.v.*), which reduced the vitality and lowered the efficiency of millions of people, has been laboriously investigated. Firm, constant, but inexpensive measures of sanitation prevent infection, and recent close study of the free-living stages of the worm points to still more effective methods of control. Schistosomiasis yields to the antimony treatment elaborated by Christopherson, and the labours of Miyairi and Suzuki and Leiper, showed that the parasites develop in water snails vulnerable to attack.

Prior to the recognition of the curative properties of intravenous antimony, kala azar (*q.v.*), which decimates rich populous tracts of Bengal and Assam, killed over 90% of those attacked. The disease is in process of investigation by a special commission, and the mode of transmission, so far baffling identification, is likely to be revealed. If the active agent proves to be a species of "sand-fly," as has been surmised, the success of the hygienic methods adopted in practice will be explained.

The progress of physiological knowledge in the special branch of endocrinology has secured success in the treatment of cases of sprue (*q.v.*), where the restoration of the calcium content of the blood has been effected by the administration of parathyroid extract.

Cholera and plague may be stayed by prophylactic vaccines, and the results of anti-typhoid inoculation were one of the medical triumphs of the World War. The incidence of tropical liver abscess has been enormously reduced by the use of emetine, and the special "liver-abscess-days"—earmarked for surgical operations—once a feature of some tropical hospitals, are now a thing of the past. Synthetic chemistry adds to the resources of the scientific physician of tropical diseases; "Bayer 205" and tryparsamide in the treatment of African sleeping sickness have given hopeful results, while new antimony compounds are replacing tartar emetic for intravenous medication, seemingly with all its advantages and none of its drawbacks. Thus the diseases which take so heavy a toll of human life are one by one yielding to science and coming under control, and the outlook to-day is brighter than even the most optimistic would have dared to prophesy some thirty years ago. In honouring the men who thus have extended the science of medicine, we should not forget those of old time who caught glimpses of truth, often through a glass darkly, but at times with a clearer vision. Of such was Donald Monro; nearly two hundred years ago he expounded methods of preventive medicine superior, in part, even to the practice followed in our own time. In these affairs, as in others, we are too apt to forget that there were heroes who lived before Agamemnon.

#### PROBLEMS OF THE FUTURE

Even should science succeed in finding a cure for every tropical disease, still other problems await solution. Can the individual be protected and enabled to work as efficiently as in a temperate zone? Can impairment of his vitality and nervous energy be prevented and normal health and longevity secured? Whether or not the tropics can be made a safe home for white settlers depends largely on the extent to which local administration will initiate and maintain effective and scientific systems of sanitation, and will educate the indigenous population into ways of cleanliness

and order. Panama sanitary methods, dependent on abundant capital and a soldierly precision of enforcement, are possible only in limited and specially favoured areas. The public health official who finds himself hampered on every hand by apathy, or worse, may dream enviously of some such despotic and off-with-his-head régime, alas, seldom realised in these days of government by enumeration of heads without regard to the cerebral content. And in certain tropical localities it is notorious that the practice of sanitary law bears little relationship to the excellence of the principles embodied in the statute-book.

When all these difficulties have been faced and overcome, and the life of white settlers modified in matters of housing, diet, work and play to meet their altered physical environment, there remains the great question: Can a white race settle permanently in a tropical country and after several generations still retain its original stamina and mental vigour? In spite of thousands of years of colonisation this question still awaits a final answer. Heretofore the results of disease—chronic malaria and ankylostomiasis stunting body and mind—moral decay, consequent on association with lower or even debased native modes of life, have been confused inextricably with the effects of climate. Who can assess the share of the climatic factor, *per se*, in the production of the “poor white”? An adverse environment alone can weaken mental and moral fibre in an astonishingly short space. Children reared in a Glasgow slum may appear a race far apart from their cousins-german, hardy fisher lads in the Outer Hebrides. Yet here there is no climatic difference to account for the observable deterioration.

The unfavourable factor in tropical climates has been variously identified as the heat, or light, rays of the sun, the depressing monotony of an equable temperature, or a high relative humidity; the last admittedly trying, and affecting both comfort and efficiency. Even so, the individual can be trained to withstand a degree of temperature intolerable before acclimatisation, but whether continued exposure to such temperatures results in some subtle change in the nervous system, with loss of vigour and driving power, is a matter of dispute. Whatever the responsible agency, certainly some diminution in vitality commonly occurs, as is evidenced by the accepted practice of granting home leave to government servants and to staffs of business concerns, and this from no motives of philanthropy but because it pays.

The history of the Dutch settlement abandoned and forgotten in the East Indian island of Kisser is often cited as evidence of successful tropical acclimatisation of Europeans, and the descendants of the settlers have been described as retaining their North Europe characteristics after 250 years of tropical life. Unfortunately for this contention, Elkington's researches show that the ordinarily accepted account of the colony is far from accurate. The Dutch colonists have inhabited Kisser only since the end of the 18th century, at the longest; moreover, four of the original nine settlers married women of coloured blood. When the island was rediscovered, the colonists were found to have retrogressed, and had lost both the Christian religion and the Dutch language. Elkington concludes that their lowered mental and physical state can be explained by the environmental conditions and acquired disease; that the measures adopted by the Dutch Govt. during recent years have resulted in definite improvement and regeneration, and that a European standard of mentality persists in substantial degree. None the less, the admixture with native blood vitiates what otherwise might rank as a conclusive experiment, at any rate so far as concerns climates resembling that of Kisser.

#### RACE PROBLEMS

When two races live in association there is a natural tendency either for the weaker to disappear, or for both to amalgamate. Such a fusion has taken place over large areas of South America, and in parts of the West Indies. But the modern Nordic man views with repugnance any mass admixture with indigenous stocks, however suitable the resulting hybrid race might prove for tropical existence. This colour prejudice, though seemingly of relatively recent origin, is deeply grounded, and in any colonisation scheme affecting North Europeans the persistence

of racial integrity is a fundamental principle (see ANTHROPOLOGY, APPLIED; COLOUR AND RACE PROBLEMS).

For reasons which need not be discussed here, the prestige of the white man has received a serious set-back of late years, and in consequence he may be excluded in increasing measure from certain tropical countries and forced to find an outlet elsewhere for his energies. In Professor J. W. Gregory's words:—

“We have seen therefore that in North America the presence of the negro has introduced problems of inscrutable perplexity; that in South America a mixed race is in firm possession; that in Africa as a whole the white man has no chance as a colonist; and that in South Africa his future depends on some complex measure of segregation. In Asia only, in the north and northwest, has the white man any prospect of permanent dominion. In contrast to those restrictions, in Australia the fundamental problem is the possibility of the occupation of the whole continent by the European race.”

The settlement of tropical Australia by whites, with the deliberate exclusion of other races, amounts to trade-unionism on a national scale, and raises questions of far-reaching political and economic import. It is not even known if such settlement and acclimatisation of white stocks is possible. We are assured in the most pragmatist manner that there is no physiological objection to the projected colonisation of tropical Australia by whites. The case, either way, is unproven, and a final pronouncement can be made only when five or six generations have been born, reared and married in tropical surroundings. Will the race then retain the qualities of temperament and nervous force inherent in white folk bred in the temperate zones? Can these peculiar characteristics persist in any race of Nordic blood who never see the snow fall? Prophecy is dangerous, and these questions cannot be answered here, nor within our lifetime. (W. P. MACA.)

**TROTSKY, LEV DAVIDOVICH** (1879–1921); Russian politician, whose real name was Bronstein, was born near Elizavetgrad, the son of middle-class Jews. He received an excellent education at the Peter and Paul *Real Schule* in Odessa and at the university of that town. Leaving the university in 1897, he was arrested as a revolutionary in the following year and soon after exiled to Eastern Siberia. In Aug. 1902 he escaped and made his way to England with a forged passport in the name of Trotsky (which name he used thenceforward). In London, despite his youth, he soon became an important member of the small body of Social Democrats which included Plekhanov and Lenin. He collaborated with the latter and others in the publication of *Iskra* (Spark), the most famous of the Russian revolutionary newspapers. In 1905 he returned to Russia, was elected a member of the St. Petersburg Soviet of Workers' Deputies and was chairman of the meeting at which the whole Soviet was arrested. He was exiled to Tobolsk but escaped immediately on his arrival in Siberia and went to Vienna, where he worked for the *Arbeiter Zeitung* and the *Pravda*. He also worked for some time in a chemical factory. In 1910 he attended the Social Democratic Congress at Copenhagen, defending a position of his own, midway between that of the Bolsheviks and that of the Mensheviks. In 1913 he was in Constantinople as a war correspondent. The following year found him in Zurich and Paris, taking part in the publication of a revolutionary paper. He wrote a book on the aims and origins of the World War which, published in German, earned him a German sentence of eight months' imprisonment. But he opposed the War not only in Germany but in the Allied countries, and in Dec. 1916 was expelled from France. He was arrested by the Spanish authorities on crossing their frontier but was presently allowed to leave for America, where he edited the Russian revolutionary newspaper, *Novy Mir* (The New World).

When the revolution broke out in March 1917 Trotsky's friends and subscribers to the paper collected the money for his journey to Russia. He was, however, arrested by the British authorities and taken ashore at Halifax, where he was interned until the Russian Provisional Govt. asked for his release. He arrived in Petrograd soon after Lenin. He was the leader of a small party of Social Democrats and soon joined the Bolsheviks, together with his followers, although he did not actually become a member of the Bolshevik party until July 1917, when he was

<sup>1</sup> Address to British Association, 1924.

arrested for being concerned in the rising which took place in that month. He played a part hardly less important than that of Lenin in organising the Bolshevik revolution in Nov. 1917 and became People's Commissar for Foreign Affairs in the new Soviet Government.

Trotsky was the most important figure in the Russian delegation during the negotiation of the Brest-Litovsk peace treaty. Believing that the moral effect of the revolution had already been such that the Germans would be unable to force their troops to move against Russia, he met the oppressive German demands with the statement that Russia would not sign a treaty on such terms but that she considered the War to be at an end and would demobilise her troops. Lenin disagreed with him, considering that the risk was too great since at that time the Germans could easily have taken Petrograd. A few days of uncertainty intervened, followed by the German advance. After a series of heated debates in the Central Committee of the Bolshevik party, Trotsky announced that he now sided with Lenin and by a majority of one it was decided to sign an even more unfavourable treaty than that which he had previously refused. Trotsky was replaced by Chicherin as Commissar for Foreign Affairs and, on taking over the Commissariat of War, he entered upon the task of creating the Red Army. In spite of opposition from many of the older Communists he made great use of officers of the old army. The results obtained by so doing were used to justify the employment of "bourgeois" technical experts in the factories. When he had made a new army that showed itself superior to those of the Whites his energies were used in preventing the complete collapse of the railways. In 1920 he organised "labour armies," using for the building of bridges and the collection of fuel armies which had been freed for such peaceful activities by their victories on the various fronts of the civil war.

Until the introduction of the New Economic Policy Trotsky urged industrial conscription, but wholeheartedly accepted the new policy which made such measures impossible. During the Polish war of 1920, he opposed the disastrous advance on Warsaw but was overruled by Lenin. In the autumn of 1923, during a discussion in the Communist party, he adopted a position whereby it was possible for the "old guard" of the Communist leaders to accuse him of canvassing for the support of the younger men. He was ill at the time but his illness did not save him from a most violent attack by Stalin, Zinoviev and others. Many of his friends were shifted from their posts and he himself was on the way to the Caucasus to take a cure, when Lenin died. Throughout the revolution the names of Lenin and Trotsky had been coupled together and the death of the one seemed to leave the other alone in the field. This was not really so. Seniority counts for much in the Communist party and the older leaders never forgot that Trotsky, in spite of his prominence, had only joined the party in 1917. The campaign to discredit him was continued and some went so far as to urge that he should be ejected from the Central Committee and even from the party. He lost his post as Commissar of War and when he returned from the Caucasus was given work of small political significance, being made head of the committee for the development of electric power in Russia. In 1925 he resigned from this post and was made head of the Central Committee for Concessions.

Trotsky stood revealed as by far the most brilliant of the revolutionary leaders, a striking orator with a gift for metaphor, an extraordinarily persuasive writer of pamphlets, an acute debater, with a power of practical organisation rare not only in the Communist party but in Russia in general. His chief recreations were writing and shooting. He wrote a number of books on the history of the revolution, on Lenin, on the civil war and on the relations between revolution and literature, besides a long series of polemic essays on questions of the day. One of the most important being *1917*, 2 vol. (Moscow, 1924) Eng. trans. of *Introduction The Lessons of October 1917* (1925). For this *Encyclopædia* Trotsky wrote the biography of Lenin. (A. R.)

**TRUMBIĆ, ANTE** (1863– ), Yugoslav statesman, was born at Spalato (Spljet). He became successively Mayor of Spalato, and deputy for the city in the Dalmatian Diet, and after 1907

deputy in the Austrian Parliament. In 1905 he and his fellow Dalmatians, Pero Čingrija, Smodlaka and Supilo, as delegates of the Croat National party, played a leading part in the movement for renewed co-operation between Serb and Croat, which culminated in the resolutions of Fiume and Zara in 1905, and in the parallel negotiations with the Magyar coalition parties. The programme of reform in Croatia, which was the basis of the agreement with Hungary, was soon frustrated by the intransigent attitude of the Wekerle Government. The Dalmatian Croats, and notably Trumbić and Supilo, consistently endeavoured to improve their relations with the Italians and to combat the constant efforts of Vienna to set the two races at variance.

On the eve of the World War Trumbić crossed the frontier to Venice, where he was joined by Supilo and several other Croat and Serb leaders. The first winter of the War he spent in Rome, hoping to win Italian official support. But Sonnino's anti-Slav policy and the secret agreement concluded between Italy and the Entente at the expense of the Yugoslavs in the spring of 1915, forced him to transfer his centre of operations to France and England. The Yugoslav committee, of which Trumbić was president, was formally constituted in May 1915 in London. In the summer of 1917 he and several of his colleagues conducted lengthy negotiations with the exiled Serbian Govt. in Corfu and representatives of all the Serbian parties, and the result was the so-called "Declaration of Corfu," which outlined the principles on which the united Yugoslav State was to be based. Through the mediation of his British friends Trumbić met representative Italians in Dec. 1917 and March 1918, and reached an agreement which became the basis of the congress of oppressed nationalities, held in Rome in April.

In the closing stage of the War the Yugoslav committee was handicapped by the narrowly Pan-Serb attitude of Pašić, and the Entente Govts. withheld their recognition of the Yugoslav programme pending a definite agreement between Pašić and Trumbić. The result was that after the collapse of Austria-Hungary the Italian claims were revived in their full force. When the provisional Yugoslav Govt. was formed at Zagreb in Oct. 1918 Trumbić was appointed Foreign Minister and peace delegate in conjunction with Pašić and Vesnić. In spite of his sane and convincing advocacy of Yugoslav claims he was unable to win the support of the Entente, which considered itself still bound to Italy by the secret Treaty of London. With the waning of President Wilson's influence, the Yugoslavs were obliged to come to a direct agreement with Italy, and the Treaty of Rapallo was signed Nov. 1920.

Trumbić's long absence in Paris, coupled with the policy of abstention pursued by the Croat Peasant party under Radić, placed him at a fatal disadvantage when the question of the new constitution came up in 1921. Trumbić voted in the minority and thereafter drifted steadily into stronger opposition to the new régime in Yugoslavia. His group formed part of the coalition "bloc" which was in power from July to Oct. 1924, and for a time he effected a working alliance with Radić and committed himself to federalism and even republicanism. The sudden *volte face* of Radić after the elections of 1925 left Trumbić somewhat isolated, as the leader of the newly constituted "Croat Federalist Peasant party."

**TRUSTS** (see 27.334).—The term trust is a convenient though mostly inaccurate label popularly applied to any large business concern, or amalgamation or association of business concerns, which exercises some degree of monopolistic power over output and prices in the industry with which it is connected. The "trust," as it first appeared in America in the 'eighties, was a form of organisation in which the shareholders of a number of enterprises agreed to assign the whole of their stock to a group of trustees, receiving in exchange trust certificates representing the valuation of their properties. Under this arrangement the trustees controlled all the businesses and could not only co-ordinate and regulate the operation of the plants thus brought under one direction, but could also dictate to some extent the output of the whole industry and the prices at which its products should be sold. Consolidations formed on "trust" lines still

exist in important industries in many countries, but they represent in Europe but a small part of the whole movement, from interbusiness competition to monopolistic combination, with which this article is concerned.

### I. THE UNITED KINGDOM

This transition from competition to combination, which has been a marked feature of industrial development the world over since the latter part of the 19th century, has in each country accommodated itself to national characteristics and conditions. In the United Kingdom great consolidations wielding monopolistic and political power have not hitherto been so formidable as in America, nor have British associations of independent manufacturers developed the range of activities displayed by such organisations in Germany. The movement toward industrial combination in the United Kingdom has been relatively more cautious and less spectacular than elsewhere. The reasons for this would appear to be partly the deep-rooted individualism of the British manufacturer and partly the greater difficulty of establishing monopolistic consolidations in a country where many of the principal industries are widely dispersed, where the raw materials of most of the great industries are drawn from world-wide sources and where such shelter as monopoly might obtain from protective import duties has not been available. None the less, combination has replaced or minimised competition over a great part of the industrial activity of the United Kingdom.

*Terminology.*—It is usual to distinguish the various types of combination by convenient labels, but the terminology is somewhat arbitrary and the distinctions sometimes without much significance. The holding company, the "combine," the vertical consolidation and the horizontal consolidation are frequently quoted types, but they are by no means mutually exclusive; and often a concern which by origin belongs to one of these categories belongs by present nature and actual operation to another. The one feature which these four have in common is that they are permanent fusions of previously independent business concerns, which, under the new régime, are under more or less completely centralised direction and control. Under the holding company arrangement each of a number of companies sells its shares to another company established for the purpose, receiving in exchange shares in the holding company.

The "combine" might be described as another name for the holding company, except that whereas the holding company may operate firms in various lines of business and may have been initiated by outside financial interests, the term combine is usually employed to designate a merging of firms previously in the same line of business at the instance of a majority of the firms or of some dominant concern among their number. Although the holding company or combine is always subject, as already mentioned, to centralised control, there are cases in which the constituent firms retain some limited measure of autonomy. The vertical consolidation is a complete merging into one industrial and commercial entity of previously independent firms engaged in the production of a commodity at successive stages of manufacture: e.g., coal and iron mining, pig iron, iron and steel, ships. The horizontal consolidation is a complete merging of previously independent firms engaged in the same line of business at the same stage of production and can only be distinguished from the holding company or the combine by having originated in the outright purchase of a number of concerns by one predominant concern in the industry or by some outside financial interest.

A more easily definable and distinct type of trade combination and one that has proved particularly applicable to British conditions, is the terminable association. Under this arrangement the firms constituting the association remain independent financial and commercial entities, but they associate for the purpose of controlling output or prices or both in the industry in which they are engaged. Such associations are properly constituted bodies having rules, constitution, officers, subscriptions, entrance fee, etc. The methods of trade regulation are various. Some associations simply fix a schedule of prices to which all

must conform; others have arrangements in regard to tenders for contract work; others regulate output by allotting to each member a fixed percentage of the total production, whatever that total may be, with penalties for exceeding the quota and compensation for falling short. Some partition out the home market, or the foreign trade, among the members, and some have from time to time reinforced their control of the markets by agreements with similar foreign associations as to the amount which shall be exported from each country to certain markets. The distinguishing feature of the association is that each component firm remains a financially separate business concern, with full freedom of action in all matters that are not ruled by the association. If under stress of circumstances, or for reasons of internal jealousy, it should break up, the constituent firms revert to their original unfettered independence.

*Permanent Combinations.*—Permanent combinations, falling into one or more of the four categories mentioned above, are found in the United Kingdom in most of the main industries and in many smaller ones. Any amalgamation of two or more business concerns might, of course, be called a "combination," but the present article is confined to those cases in which the combination produces a concern of such predominance in its industry as to give it some degree of monopolistic power. It has been asserted that any consolidation or association which covers 80% of the output of an industry can dictate the prices at which the other 20% shall sell its competing products and so may be described as having an effective monopoly; but that formula cannot be applied indiscriminately, inasmuch as the limiting conditions of control vary greatly from industry to industry and in some industries very effective monopolies of merely local range may exist. It must suffice here to mention a few outstanding examples of consolidations in a position to exercise some degree of monopolistic power. In the cotton branch of the textile industry great amalgamations of previously independent firms are to be found. Messrs. J. & P. Coats have long occupied, as a result of growth and absorption, a pre-eminent position in the sewing-cotton industry. The Fine Cotton Spinners' and Doublers' Association is a mammoth amalgamation, dating back nearly 30 years. In the cotton spinning and manufacturing branches two other great amalgamations have come into being since the War, The Amalgamated Cotton Mills Trust and Crosses and Winkworths, in both of which previously independent concerns have been merged.

*Principal Industries.*—In the woollen and worsted industries combination has taken the form rather of association than consolidation; but Woolcombers Ltd. is an amalgamation dating back some years, while since the War large amalgamations have been formed in the worsted spinning and knitting wool spinning sections of the industry.

In textile bleaching, dyeing, printing and finishing the combine type of consolidation prevails. The three largest combines are the Bradford Dyers' Association, the Bleachers' Association and the Calico Printers' Association; all these had their origin in the early days of the century. In view of the terminology adopted above in describing the various types of combination, it should perhaps be emphasised that these are not terminable associations but permanent amalgamations. Two other combines in this industry are the British Cotton and Wool Dyers' Association and the English Velvet and Cord Dyers' Association.

In the chemical industry, Brunner Mond and Company and the United Alkali Company are predominant concerns in the manufacture of heavy chemicals. Lever Brothers, British Dyestuffs Ltd., the Salt Union, Borax Consolidated, and Nobel Industries Ltd. are each dominant in their respective branches of industry.

In the coal industry amalgamation has not proceeded far, except in South Wales, where there are two large groups of anthracite collieries, merged under Amalgamated Anthracite Collieries Ltd. and United Anthracite Collieries Limited. A pre-War Welsh combine is the Consolidated Cambrian Limited. Colliery combines are only to be found in occasional instances in England and Scotland.

In the iron and steel industry combination by terminable association has been accompanied by great concentrations of capital, such as Dorman Long & Co., Bolckow, Vaughan & Co., Baldwin's Ltd., the Ebbw Vale Co., Guest, Keen and Nettlefolds, the United Steel Companies Ltd. and Richard Thomas & Company. All these are what have been described as vertical consolidations, but in fact the merging which they embody has been on both the horizontal and vertical planes.

The engineering and shipbuilding industries, again, present a network of terminable associations studded by large consolidations. Foremost among these are Vickers Ltd., Armstrong Whitworth & Co., Cammell Laird & Co. and John Brown & Co., but a score more could be quoted within almost the same range of importance. Most of these great amalgamations are of pre-War origin; but they acquired additional properties during and since the War. In the post-armistice boom period some new amalgamations of considerable importance were formed.

Only a few of the principal industries are dealt with above. In other industries examples of dominant consolidations are to be found, notably in matches, glass bottles, electric lamps, shoe-making machinery, glass and tobacco.

*Other Associations.*—Preceding paragraphs have dealt with consolidations. As regards the terminable associations, it would avail little to mention even the most important by name or to describe their individual activities. Suffice it therefore to say that associations of manufacturers and traders for the regulation of prices or output or both are found in most, if not all, branches of British industry and trade. Even in industries already dominated by a single large consolidation there is usually to be found a trade association, of which the dominant concern is a member, and through which it can exercise more directly than otherwise its influence upon the industry as a whole.

The consolidation and the association by no means exhaust the catalogue of arrangements whereby trade and prices may be controlled. The "gentlemen's agreement" or "honourable understanding" may in favourable circumstances be as powerful an instrument for minimising competition as a formal organisation. Interlocking directorates, with or without exchange of shares, may result in two or more companies coming under concerted control without any outward change in constitution. Other examples of the tendency towards concentration of capital and economic power will be seen in the great banking amalgamations, in the multiple shop system, in the tied house system in the licensed trade and in the control exercised over tobacco, meat and other commodities by interests domiciled outside as well as inside the United Kingdom. The amalgamations of shipping companies and the maintenance of liner freights by the shipping rings are other long-standing examples of the concerted control.

The degree to which combination has supplanted competition as the ruling factor of business operations should not be over-estimated. Even in the most powerfully organised industries competition plays its part with fitfully recurring intensity; while there are still industries (e.g., coal, shipbuilding, textile manufacturing, as well as a host of minor industries) in which the concerted control of output or prices has made relatively little headway. But the steady trend is toward increased combination. Under the influence of war conditions not only were numbers of listless associations galvanised into greater activity and enterprise, but many new associations were formed. Also, one effect of the excess profits tax was to encourage the buying up of unprofitable businesses by prosperous concerns, for such purchases were in effect paid for by moneys which would otherwise have gone in excess profits duty to the revenue. For this and other reasons the war period was one of unusual increase in the number of amalgamations.

*Advantages and Disadvantages of Combination.*—Industrial combination has undoubted advantages. By combination substantial economies can be effected in buying, manufacturing and selling. As regards the buying of material and components, purchases can be made in gross instead of in detail, with the advantages of better selection, better terms and lower transport charges; middlemen can be side-stepped and, if need be, the control over the sources of material can be acquired. As regards manufacture, parts can be standardised and made interchangeable, with consequent economies and benefits, sectional specialisation can be developed, orders can be more advantageously distributed and the whole of the plant and methods of production can be raised to a uniformly high level. As regards selling, the wastes of competitive salesmanship and advertising can be greatly diminished, and a serviceable selling organisation, inspired by the interests of the industry as a whole, can be instituted. Along

with all this goes another advantage; the wider and freer spread through the industry of what would otherwise have been jealously guarded knowledge of processes and costs.

Against these possible gains on the score of productive and distributive efficiency must be set some possible losses. Where an industrial unit grows beyond the compass of one man's personal detailed direction, "system" must be introduced, and system can degenerate into bureaucracy and red tape. What is gained in power and knowledge at the centre may be lost in freedom and strength at the circumference, and the over-grown unit is in constant danger of becoming inefficient and reactionary. Again, under the shelter of monopoly a comfortable somnolence may descend upon the giant concern, the fear of change is a well-known characteristic of large administrations, and the large business unit may become stagnant and even reactionary, especially if its control falls increasingly into aged hands. But whatever the balance of these influences may eventually be—greater or less productive efficiency—combination brings in its train the further danger of monopoly power being used to exact monopoly prices and conditions from the public. The problem as seen by British eyes has therefore been one of how to leave business concerns free to achieve the economies and other advantages of combination in so far as they are consistent with the general interest, and at the same time to provide means of curbing any tendency to use monopoly power detrimentally to the public and of penalising those who do so use it.

*The Committee on Trusts.*—The policy of "declaring war on the trusts" has found little informed advocacy in the United Kingdom. American experience of repressive legislation as embodied in the Sherman and Clayton Anti-Trust Acts has been observed, but without admiration. The committee on trusts, appointed by the Minister of Reconstruction in Feb. 1918, turned its attention rather to what might be called "policing" action than to repression. It sought for ways in which combinations might be controlled or supervised to safeguard the public interest from the abuse of monopoly power while being otherwise left free to achieve all those economies and improvements which combination alone can furnish.

Public ownership, public control, public competition, profit limitation and profit taxation were passed under review. In all these suggested schemes three main difficulties were encountered at the outset: first, that of defining a monopolistic concern; second, that of distinguishing rightful rewards of enterprise and efficiency from the exactions of monopoly; and, third, that of determining the datum on which rate of profit can be calculated. These suggestions were one by one rejected as limited in scope, difficult of application, or hazardous in reaction, and the committee turned its attention in other directions. It was thought that if fuller publicity in regard to the conduct and earnings of business concerns generally, and of the working and effects of combinations in particular, could be secured, the desired object would be in great measure achieved. It was also thought that some machinery should be provided whereby suspected or alleged abuses could be penalised.

Accordingly, the conclusion was reached that there should be established a department of state charged with the duty of informing itself as to the nature, extent and development of combination of all kinds in so far as they tend to the restraint of trade and the creation of monopolies, and of making preliminary inquiry into complaints made in regard to them; also that a tribunal should be set up to which the department could apply for powers to obtain particular information, and would refer for full investigation cases in which combinations appeared to act injuriously to the public interest. The requisite publicity would thereby be secured in two ways: the relevant facts as to offences proved before the tribunal would be made public, and the department would present annually to Parliament a report upon the nature, extent and development of combinations. Publicity thus secured would not only be in itself a considerable safeguard against the abuse of monopolistic power, but it would serve to reveal actions and developments for which publicity alone was not a sufficient safeguard, and against which further action should be taken, whether in the form of nationalisation, public competition or the control of prices and profits. These conclusions formed in substance the recommendations of the committee; but down to the end of 1925 they had not been made the subject of legislation.

Until the appointment of the committee on trusts no official investigation of the problem presented by the growth of combination in British industry generally had been made. The Report of that Committee, with its appendices, afforded for the first time to Parliament and the public authoritative information as to the position. Subsequently committees appointed under the Profiteering Acts of 1919 and 1920 issued reports upon particular industries in which much detailed information was embodied. These reports

constitute a mine of information for the student of industrial combination in the United Kingdom.

**BIBLIOGRAPHY.**—*Report of the Committee on Trusts* (Cd. 9236 of 1919), with *Memoranda* by Mr. John Hilton, Mr. Percy Ashley and Sir John Macdonnell. Reports of 57 committees appointed under the Profit-sharing Acts 1919 and 1920. A list of these reports, together with a survey of the work done by the committees, will be found in a report—*The Work of the Central Committee* (H.M. Stationery Office, 1921). Other official publications bearing closely on the subject are the *Report of the Royal Commission on Food Prices* (Cmd. 2390, 1925); *Reports of the Committee on Industry and Trade* (1925 and 1926); various *Reports* by committees appointed under the Safeguarding of Industries Acts; *Reports* on the coal industry and coal prices by committees appointed by the Mines Department (1923 and 1924); the *Linlithgow Reports* on the distribution and prices of agricultural produce by committees appointed by the Minister of Agriculture (1923 and 1924); *Reports* on prices of building materials by Ministry of Health and Board of Trade (1923 to 1925); *Report of the Royal Commission on the Coal Industry* (1926). The best account of industrial combination in the United Kingdom before the War is given in H. W. Macrosty, *The Trust Movement in British Industry* (1907). (J. H.)

## II. THE UNITED STATES

The Sherman Anti-Trust Act of 1890 did not satisfy the popular demand for corporate control. The rapid industrial development brought about an even fiercer competition, which in turn brought about many consolidations. Between 1898 and 1901 there were an extraordinary number of consolidations which, while checking many of the evils of excessive competition, were attended also by many of the evils that are an inevitable part of great and sudden prosperity. With consolidation came power and sometimes the temptation to use it without a nice regard for business ethics. Moreover the feverish consolidation of business gave added impetus to the labour movement, resulting in the employment by organised labour of methods no less reprehensible than were some of the practices of their employers. To meet this situation President Wilson recommended to Congress, Jan. 20 1914, a comprehensive programme of trust legislation, embracing: (1) Laws to prevent the interlocking of the directorates of competing corporations; (2) a law giving the Interstate Commerce Commission power to superintend and regulate the financial operations of railways; (3) a legislative definition of the meaning of the Anti-trust law and of the practices prohibited thereunder; and (4) the creation of a Federal Trade Commission as a fact-finding agency for the guidance of business and the public.

**Trade Commission Act.**—This programme was embodied in three bills: the Federal Trade Commission bill, the Clayton bill and the Railroad Securities bill. The last-named measure was postponed on account of the disturbed conditions created by the War, but the Trade Commission bill was approved on Sept. 26 1914 and the Clayton bill on Oct. 15 1914. The Trade Commission Act provides for a Federal Trade Commission of 5 members vested with powers of regulation and investigation. It is empowered to prevent persons, partnerships and corporations, except banks and common carriers subject to the commerce acts, from using unfair methods of competition in commerce; to investigate and gather information concerning the organisation, business conduct, practices and management of any corporation engaged in commerce, except banks and common carriers; to investigate and report, upon the direction of the President or of either House of Congress, the facts relating to alleged violations of the anti-trust laws by any corporation; to investigate and make recommendations, upon application of the Attorney-General, for the adjustment of the business of any corporation alleged to be violating the anti-trust laws, to investigate trade conditions in and with foreign countries, where these conditions may affect the foreign trade of the United States, and to report to Congress thereon with such recommendations as it deems advisable. The important business practices which the commission regards as unfair methods of competition are: misbranding, local price cutting, use of bogus independents and "fighting brands," full-line forcing, boycotting and black-listing, espionage, commercial bribery, false and misleading advertising, false labelling, rebates and coercion.

**Clayton Act.**—The Clayton Act forbids, where the effect is substantially to lessen competition or to tend to create a monopoly in interstate or foreign commerce: (1) discriminations in price between purchasers of commodities; (2) exclusive purchase and sale arrangements in connection with any patented article; (3) the acquisition by a corporation engaged in commerce of the stock of a competing corporation, except solely for investment purposes or the formation of subsidiary corporations to carry on their immediate lawful business; (4) interlocking directorates in corporations engaged in whole or in part in commerce, other than banking and trust companies and common carriers, whose capital surplus and undivided profits aggregate more than \$1,000,000, if such corporations are or have been competitors. The remedies provided against the violation of these provisions are: (1) enforcement by the Interstate Commerce Commission where applicable to common carriers, by the Federal Reserve Board where applicable to banks, banking associations and trust companies and by the Federal Trade commission where applicable to all other character of commerce; (2) suits by the U.S. Govt.; (3) suits by individuals for three-fold damages; and (4) suits by individuals for relief by injunction.

The Clayton Act further contains certain provisions desired by organised labour. These provisions, it was popularly believed, gave labour certain immunities not enjoyed by any other class. Section 6 of the Act declares

... that the labour of a human being is not a commodity or article of commerce. Nothing contained in the Anti-trust laws shall be construed to forbid the existence and operation of labour, agricultural, or horticultural organisations, instituted for the purposes of mutual help, or to forbid or restrain individual members of such organisations from lawfully carrying out the legitimate objects thereof; nor shall such organisations, or the members thereof, be held or construed to be illegal combinations or conspiracies in restraint of trade, under the Anti-trust laws.

Section 20 limits the use of the injunction in labour disputes, and legalises strikes, picketing and boycotts, when carried out in a peaceful and otherwise lawful manner. The courts have held that these provisions do not introduce any new principle into the equity jurisprudence of the Federal courts, but they are merely declaratory of what was the best practice always.

**Cotton Futures.**—On Aug. 18 1914 a Cotton Futures Act was approved, which levies a tax upon all contracts for the sale of cotton for future delivery, except such as comply with certain prescribed conditions, such as specifying the grade, the prices paid, etc. It is required further that standard grades shall be delivered and full weights tendered. Disputes shall be settled in accordance with rules and regulations prescribed by the Secretary of Agriculture.

**War Measures.**—The effect of the War experiences upon the attitude of the public toward combinations was marked. The first act of the Secretary of the Treasury when the railways were placed under his charge was to order that they all be managed as one system. The emergency of war showed at once the economic mistake of the Interstate Commerce Act of 1887 in forbidding pooling under proper restrictions, a mistake to which the Interstate Commerce Commission had from its beginning called attention. Again, the services most efficiently rendered by such organisations as the leading packing companies, the great steel corporations, the American Telegraph and Telephone Co. and others, services that could not possibly have been so promptly rendered by any number of smaller competing companies, showed clearly to the general public—and, one may add, made clear also to the courts—the real advantages that may lie in consolidation. This change in public opinion has been clearly shown in the trend of later legislation and court decisions.

**Other Legislation.**—The Webb-Pomerene Act of April 10 1918 exempted export trade associations, not operating so as to restrain trade or to enhance or to depress prices within the United States, from the operation of the Anti-trust laws placing them under the supervision of the Federal Trade Commission; and the Capper-Volstead Act of Feb. 18 1922 extended similar exemption to agricultural associations, provided such associations operated for the mutual benefit of their members as producers;

and placed them under the supervision of the Secretary of Agriculture.

The Packers and Stockyards Act of Aug. 15 1921 classified packers, commission merchants and stockyards for special regulation under the direction of the Secretary of Agriculture. These businesses are held to be agencies of interstate commerce, and as such are subjected to the affirmative law of public service. It is unlawful for them to engage in or use any unfair, or to manipulate or control, prices, to create a monopoly or otherwise to restrain interstate commerce. Similar regulations were extended to boards of trade by the Grain Futures Act of Sept. 21 1922. The Act forbids the use of any interstate instrumentality of commerce or communication in offering or accepting sales of grain for future delivery or to disseminate prices or quotations thereof, except by the man who holds the grain he is offering for sale, or by the owner or renter of land on which the grain offered for sale is to be grown, or by members of boards of trade located at a terminal market on which cash sales occur in sufficient volume and under such conditions as to reflect the general value of grain and its different grades, and which have been designated by the Secretary of Agriculture as "contract markets." Besides this national legislation there have been numerous state laws, or amendments to state laws, regulating the intra-state activities of industrial combinations and trusts, resulting in much duplication of effort, some conflict of jurisdiction and considerable inconvenience to business.

*The Relations of Government and Business.*—The result of this anti-trust legislation, especially the early legislation, has been to take the Government more and more into business and business into politics, thus creating evils in many ways as serious as those which the laws were designed to correct. Furthermore, the Government has been only partially successful in preventing unfair business practices and in maintaining effective competition in business where such competition is desirable. To meet this situation there is now well under way a movement from within business to remove the causes for public regulation. This movement is based upon the theory that no matter how wisely conceived or how efficiently administered governmental regulation of business may be, it can never be as effective as regulation by business itself from within. In pursuance of this policy of industrial self-government, many trades, acting through trade associations, have formulated fair business practices codes and there have been organised voluntary co-operative agencies for investigating and prosecuting false advertising and the many forms of commercial fraud. In line with this practice is a procedure instituted by the Federal Trade Commission in 1919, under which the trade submits its trade practices to the commission for that body's information. The commission makes no ruling, but for its own information it requests the members of the trade to put into concrete form their conclusions as to the practices regarded as unfair and in several instances it has instituted formal proceedings against those who refused to conform to the standard practice.

Numerous suggestions have been made to bring about joint action between producers and distributors to eliminate business wastes. To this end the Department of Commerce has co-operated effectively. Many national trade associations are furnishing to it business data which are published monthly and the Bureau of Standards is engaged in the work of standardisation and of co-operative research with many of these trade associations, which result in enormous annual savings to business and to the Government.

*Decisions of the Supreme Court.*—These attempts at self-improvement on the part of trade associations, and the co-operation of these associations with the Government in the ways noted, indicate a new trust policy in the process of evolution, a policy involving less persecution and more co-operation. In 1911 the Supreme Court in *United States v. Standard Oil Company* (221 U.S. 1) applied the rule of reasonable construction to the Sherman Anti-trust law, holding that only contracts and combinations that were in unreasonable restraint of trade at common law are illegal. In 1920, in *United States v. United States Steel Corporation* (251 U.S. 417) this court refused to regard the mere size of a corporation as of itself illegal, and intimated that it did not approve prosecutions under the anti-trust laws that

did not serve the public interest. And in 1925 two decisions of far-reaching importance to the industrial life of the country were given (*Maple Flooring Manufacturers' Association v. United States* and *Cement Manufacturers' Association v. United States*, 45 Sup. Ct. 578), holding that "trade associations or combinations of persons or corporations which openly and fairly gather and disseminate information as to the cost of their product, the volume of production, the actual price, stocks of merchandise on hand, approximate cost of transportation . . . and who . . . meet and discuss such information and statistics without however reaching or attempting to reach any agreement with respect to prices or production or restraining competition, do not thereby engage in unlawful restraint of commerce." Similar trade association activities had been held illegal in 1914 and 1921 (234 U.S. 600; 257 U.S. 377).

It is also significant that comparatively few of the corporations cited for violation of the anti-trust laws since 1910 were what are popularly known as "trusts." It is big business that is setting the higher standards. These higher standards have long been advocated by economists and by many of the great leaders of the large combinations, but the change of policy has doubtless been affected also by the tremendous increase in corporate stockholders in the years 1915-25, a movement largely instigated and furthered by special offers of stock in some of the largest corporations to their employees or of gas companies to their customers. In the meantime no amount of regulation has materially checked the integration of American business from the small independent factory, performing but a single step in the process of production, to the horizontally and vertically organised super-combinations of to-day, tending to become complete and self-sufficient industrial units. (See also CARTELS; FEDERAL TRADE COMMISSION; INTER-STATE COMMERCE.)

**TSCHAKSTE, JAN** (1859— ), first president of the Republic of Latvia, was born in Courland Sept. 14 1859. He was educated at the Mitau gymnasium, studied law at the university of Moscow, and was for some years in the public prosecutor's department of the Courland Government. Leaving the public service in 1888 he started practice as a barrister in Mitau and began to edit the paper *Tēvija* (Fatherland). In 1902 he served on a committee appointed by the local administration to inquire into agricultural conditions in Courland, and from time to time was employed on various Imperial Govt. committees. In 1906 he was elected a member of the first Russian Duma. The German invasion of Courland, July 1915, obliged him to leave Mitau. He went to Petrograd (Leningrad) where he founded a central relief committee for war refugees. In 1916 he went to Stockholm to promote the cause of Lettish independence and published there in German, his book *Die Letten und ihre Latvija*.

In 1918 Tschakste was elected chairman of the People's Council and was later head of the delegation sent to Paris and London to secure the recognition of the Republic of Latvia. In 1920 he was president of the Latvian National Assembly, and also became professor of international law at the University of Riga. On Nov. 14 1922 he was unanimously elected president of Latvia by the first Latvian Saeima (Parliament), and on Nov. 6 1925 was re-elected for a further period of three years.

**TSINGTAO, CAPTURE OF.**—The first part which Japan took upon herself to play in the World War was the reduction of the German stronghold of Tsingtao, on the bay of Kiaochow. This fortress served at the outset of the War as the only base of operations in Eastern Asia for the German marauders menacing the Allied trade routes. It was imperative to make Von Spee's raiders homeless, and the military and naval operations against

the redoubtable base, which was under the command of Capt. Meyer-Waldeck and garrisoned by some 13,000 men, of whom 5,599 were German regulars, were started with the utmost dispatch. On Aug. 27 1914 the blockade of Kiaochow Bay was declared by the Japanese Navy, and Lungkow, 150 m. north of Tsingtao, was chosen as the point for landing troops.

On Sept. 2 1914 the Japanese division, under the orders of Lieutenant-General Kamio, commenced landing at Lungkow. Despite the terrible weather conditions, the vanguards arrived on the 12th at the small town of Tsimo, where they encountered the enemy for the first time. The second Japanese contingent began to land at Laoshan Bay, within the leased zone, on Sept. 18 and soon established touch with the I. Army. The Japanese forces under General Kamio thus amounted to about 22,980 officers and men, and they succeeded in some 10 days in wresting from the Germans several of their advanced positions. On Sept. 24 there arrived at the arena of campaign the British force, commanded by General Barnardiston, consisting of 910 officers and men of the 2nd South Wales Borderers and 450 of the 36th Sikhs. After the non-combatants had been permitted to leave the fortress, the general attack on the position was commenced on Oct. 31, the Japanese blockading fleet off the harbour assisting by a continuous bombardment. On the morning of Nov. 7 white flags were descried on the forts of Moltke, Bismarck and Itis, to the pleasant surprise of the attacking army, which had expected a protracted siege. After the fall of the stronghold it was ascertained that all enemy ships, including the Austrian cruiser "Kaiserin Elisabeth," had been sunk in the port of Tsingtao. The Japanese Army lost, during the campaign, 1,968 killed or wounded, and the Japanese Navy a cruiser, a destroyer and a torpedo boat. The port of Kiaochow was reopened for trade by the Japanese on Dec. 28 1914. (See WORLD WAR: BIBLIOGRAPHY.)

**TUAN CHI-JUI**, Chinese politician, was born in Anhwei and graduated from the Peiyang military school. Rising rapidly, he was largely responsible for the re-organisation of the Northern Army and after succeeding Yuan Shih-kai as viceroy of the Hukuang Province, he became commander of the I. Army. He was one of the military leaders who signed the memorial of Jan. 1911, urging the Emperor to abdicate, and joined the first Republican Cabinet in Nov. 1912 as Minister for War. He was acting Premier from May to July 1913, Minister of War again in 1914, and Premier in April 1916. In May 1917 he was dismissed by Li Yuan-hung, but the failure of Chang Hsun's attempt to restore the monarchy brought him back to office. In Oct. 1918 he resigned, and, after an ill-advised coup on behalf of the Anfu Club, played no great part in national affairs till Nov. 24 1924, when he succeeded Tsao Kun as President.

**TUBERCULOSIS** (see 27.354).—Tuberculosis is a disease of man and animals caused by the tubercle bacillus, which belongs to the "acid-fast" group of bacteria, some of which are pathogenic and others quite harmless. The most important pathogenic varieties are the "human," the "bovine" and the "avian." Whether these are to be regarded as distinct organisms or merely as mutations is not yet settled but they are easily distinguished by their selective effects on test animals.

Tuberculosis, when it has reached the stage at which it is clinically recognisable, may be regarded as the end-result of a slow progressive and long unrecognised bacterial invasion. It should never be forgotten that, in the majority of infected persons in civilised communities, this clinically recognisable end-stage is never reached; in other words, only a small proportion of the number of infected persons becomes clinically tuberculous.

*Distribution Throughout the World.*—A world-survey shows that tuberculosis tends to be wide-spread in densely populated areas linked by commercial and social ties with the outside world, and is rare or absent in sparsely populated and culturally isolated communities. Climatic, geological and racial factors appear to play a secondary part. Density of population, with the opportunities for frequent and close contact with infective persons which it involves, appears to be all-important in the dissemination of the germ, while wages, occupation, housing, diet, climatic conditions and racial customs constitute ancillary factors of varying significance in so far as they bear upon the capacity of the individual to resist the infective dose or doses to which he has been subjected.

With human tuberculosis, it is where men are herded together in the centres of industry that the infection becomes so common as to be almost universal. That this statement is true is proved by the post-mortem findings of reliable pathologists in Europe and America who have investigated long series of cadavers of persons dying from all diseases. In the words of M. Fishberg "no matter what the cause of death may have been, whether the persons knew they had tuberculosis or not, between 50 and 100% of people living in large cities show active, quiescent or healed tuberculous lesions in some organ of their bodies."

These findings bring into sharp relief the importance of the distinction between infection and disease. The results of tuberculin tests applied to healthy persons (Pollak, Vienna, 1911; Mantoux, Paris, 1909 and 1910; Fishberg, New York, 1914; Calmette, Lille, 1911 and others) show that, by the age of 15 years, nearly every individual living under urban conditions has already become infected with the tubercle bacillus.

It is clear, therefore, that, in densely populated countries, tuberculous infection is far more widespread than tuberculous disease. In sparsely populated and isolated countries, on the other hand, neither tuberculous infection nor tuberculous disease is common. Borrel, for instance, found that only 3% of the Senegalese soldiers summoned to Europe for the World War gave a positive response to the tuberculin skin-test on arrival in France, while numerous investigations carried out in the African and Asiatic Colonies and Dependencies of the European Powers show that primitive tribes living under their natural conditions are almost free from tuberculosis.

It has frequently been shown, however, that the members of these primitive communities, on quitting their native surroundings and coming into contact with the "tuberculised" populations of Europe, tend to show a marked susceptibility to tuberculosis; the clinical course, in these cases, being of a rapidly progressive and usually fatal type.

It would seem, in fact, that, where there has been little or no previous exposure to infection, the individual remains completely unprotected against tuberculous disease, while, on the other hand, there is manifest in the members of communities in which tuberculous infection is wide-spread, a considerable power of resisting the development of the tubercle bacillus and of rendering latent the active foci of infection.

*Clinical Manifestations.*—The primary clinical manifestations of tuberculosis tend to vary with the portal of entry of the bacillus. In uninfected subjects, the germs can pass through the mucous membranes of the respiratory and alimentary tracts, without causing, at the moment, any marked local disturbance and their transit thence is easy along lymphatic channels to the nearest lymphatic glands. In these glandular filters, the tubercle bacilli tend to be arrested and there they pullulate and set up the first foci of disease.

The formation of secondary foci of infection depends upon the spread of tubercle bacilli from their primary foci in the lymphatic glands to other tissues and organs. The presence of secondary foci thus implies a generalisation of the infection chiefly by way of the blood stream. This generalisation can take place much more easily in susceptible persons than in those who are more resistant, and in the young than the old. Thus the tendency to widely disseminated tuberculosis is much more marked amongst those groups of individuals in which the "tuberculin test" shows the highest proportion of negative results.

In the infants and young children of European and American communities, the proportion of bone and joint tuberculosis and of tuberculous meningitis is far higher than in adults; while, in the adults of "primitive" communities, brought for the first time into contact with infection, the same tendency to wide dissemination of lesions is always found.

The *reactive intolerance* implied in a positive response to the tuberculin test which is only acquired as the result of a preceding infection, constitutes a factor of supreme importance in limiting the spread of tubercle bacilli within the body, by causing local inflammation, cell-proliferation and finally fibrosis, with arrest of the wandering germs and their confinement within a fibrous or calcified area. And this reactive intolerance is manifested, not only toward endogenous re-infection from pre-existing foci but to exogenous re-infection from outside the body.

*Pulmonary Disease.*—With this conception in mind, it is not difficult to understand why the tuberculosis of adult life in civilised and

"tuberculised" communities usually takes the form of pulmonary disease. In the generalisation of infection through the blood stream from the primary lymph-gland foci, the bacillary emboli must travel along the veins from the glands and since all the venous blood must necessarily pass through the capillary bed of the lungs before being re-distributed throughout the body, the lung tissue presents the first filter to be encountered by the blood-borne bacilli. It is into the lungs, too, that all contaminations are drawn in respiration. While both blood-borne and air-borne tubercle bacilli may pass unchecked through the "virgin" lung-tissue of children and non-infected adults, they tend, where "reactive intolerance" exists, to be arrested in the pulmonary tissue and to set up the inflammatory and ulcerative phenomena of phthisis.

### I. IN GREAT BRITAIN

*Changes in Clinical Type.*—The statement is frequently made that the cases of pulmonary tuberculosis encountered 30 or so years ago were much more acute than those seen to-day, and a general impression exists amongst clinicians that phthisis is more acute even now in parts of Ireland, Scotland and Wales than in London and the big industrial centres. This clinical impression receives strong support from the statistical inquiries of J. Brownlee (M.R.C. Special Report Series No. 18, 1918), who has shown that, in males especially and to a less extent in females, the age-period of maximum death-rate has steadily receded from the "young adult" group to the "middle age" group in the succeeding decennia from 1851-60 to the present time.

This diminution of the "young adult" type of death-rate has, however, been less marked in certain counties of Ireland, Scotland and Wales, and indeed, in agricultural communities everywhere, than in the larger centres of population. Brownlee, in the report quoted, suggested that these differences might be due to the existence of para-tubercle bacilli of unequal virulence, but later researches by Tulloch have failed to discover any antigenic variants in a large series of "human" tubercle bacilli investigated by him. It may be assumed, therefore, that the recession of the age-period of maximum mortality from early adult to later life implies a more protracted clinical type of pulmonary tuberculosis now than formerly and in the larger centres of population as compared with the more sparsely populated agricultural districts.

*Fall in Tuberculosis Mortality.*—As will be seen from the appended table (extracted from the registrar general's *Statistical Review of England and Wales for the Year 1924*, Table 6, page 35) there has been, from 1838 onwards, a steady fall in the tuberculosis death-rate affecting both the pulmonary and all other forms of the disease. This fall, which has been observable in other civilised countries, though often claimed as evidence of the value of modern methods of prevention, was just as marked before the recognition of the infective nature of tuberculosis as after the discoveries of Villemin and R. Koch had given a definite direction to sanitary effort. Clearly therefore, some factor of natural adaptation must have been present to supplement the efforts of preventive medicine.

TABLE I. *Annual Mortality at All Ages Per Million Persons Living*

| Period               | Tuberculosis (All forms) | Tuberculosis of (Respiratory System) |
|----------------------|--------------------------|--------------------------------------|
| 1838-42 (5 years)    | 4,419                    | 3,782                                |
| 1847-50 (4 years)    | 3,714                    | 2,889                                |
| 1851-5               | 3,638                    | 2,805                                |
| 1856-60              | 3,323                    | 2,572                                |
| 1861-5               | 3,313                    | 2,527                                |
| 1866-70              | 3,201                    | 2,447                                |
| 1871-5               | 2,942                    | 2,217                                |
| 1876-80              | 2,817                    | 2,038                                |
| 1881-5               | 2,543                    | 1,830                                |
| 1886-90              | 2,324                    | 1,635                                |
| 1891-5               | 2,122                    | 1,461                                |
| 1896-1900            | 1,906                    | 1,323                                |
| 1901-5               | 1,743                    | 1,218                                |
| 1906-10              | 1,566                    | 1,106                                |
| 1911-5 <sup>1</sup>  | 1,414                    | 1,047                                |
| 1916-20 <sup>1</sup> | 1,441                    | 1,107                                |
| 1921                 | 1,126                    | 884                                  |
| 1922                 | 1,121                    | 889                                  |
| 1923                 | 1,062                    | 836                                  |
| 1924                 | 1,058                    | 841                                  |

<sup>1</sup> The mortality for the years 1915-20 relates to civilians only.

The foregoing table is taken from the registrar general's *Statistical Review of England and Wales for 1924*.

Those who favour the theory of an "hereditary disposition" to tuberculous infection see in this diminution of mortality the result of the dying off of susceptible stock and the survival of the more resistant. Others consider that, with the wide dissemination of infection resulting from the agglomeration of large numbers of persons into urban communities, there has been at work a factor of natural auto-immunisation, individuals acquiring various degrees of resistance as the result of mild and repeated infections.

In favour of the latter theory, it may be said that "acquired immunity" plays a part in limiting the spread of other bacterial diseases, that even the most susceptible animals may be made relatively resistant to tuberculosis through mild laboratory infections and that a high degree of resistance in any given community, as evidenced by a relatively low death-rate and a relatively chronic clinical type, goes hand in hand with a wide diffusion of infection as proved by tuberculin tests.

*Prevention.*—Man is liable to infection from two main sources, the first and infinitely the more important being infected persons and the second, milk from infected cows.

Not all infected persons are equally infective. Those suffering from the chronic type of pulmonary disease with cavities are, perhaps, the most dangerous of all, such cases producing, as a rule, copious expectoration of a sputum heavily charged with bacilli while, being relatively resistant, they often survive for years and are well enough to remain at home. There exist, too, cases whose symptoms are more suggestive of chronic bronchitis or asthma than of tuberculosis and who consequently remain undiagnosed, no precautions being taken. Not only the sputum of such persons but the droplets emitted in coughing and talking are sources of danger to others, while the excreted bacilli may accumulate on the clothing and bedding used by them and in the apartments which they occupy.

Such persons establish the greatest concentration of infective matter within the home, and the smaller, the worse ventilated and the more crowded the home, the more massive the infection and the more serious the danger to others. In the home contact with susceptible persons is most likely—for the home is the nest for infants and young children. It is upon the homes and the families of infected persons that preventive measures must be focussed.

Adequate provision of hospital and sanatorium accommodation is also a prime necessity so that infected persons may be removed from amongst their still healthy relatives. The use of sputum flasks, the ventilation of rooms, provision of good food for dependants—all these will help. In France, promising results are being attained on the Grancher System by which the young children of tuberculous parents are placed with selected foster parents in country districts.

Another interesting line of prophylactic effort now under trial in France is the protection of the infants born to tuberculous parents by "vaccination" with living but attenuated tubercle bacilli. A. Calmette and C. Guérin have succeeded, by special cultural methods, in so reducing the virulence of a selected bacillary strain that it no longer produces tuberculosis but merely a transitory and benign infective process accompanied, however, by the development, in experimental animals, of a high degree of resistance against re-infection by virulent strains. This vaccine of Calmette (B.C.G.) is now being administered not only to calves but to the infants of tuberculous parents shortly after birth. So favourable have been the results of experiments on laboratory animals that there are real grounds for hope, both as to prevention of human and bovine tuberculosis. But it will take years to evaluate the success or failure of these experiments. In the interval, the want of any specific preventive measure throws us back upon general measures of hygiene, attempts to diminish the pool of infective persons by improved methods of treatment and the supervision, control and, where possible, isolation of infected persons through the machinery of the tuberculosis schemes of local authorities and by precautions against the sale or the use of milk containing living tubercle bacilli.

General measures of hygiene find their most important application in arrangements for the conscientious notification of diagnosed cases, the inspection of "contacts," the medical inspection of school children, the provision of "clean milk," the betterment of housing, the adequate disinfection of contaminated articles and places and tactful and efficient "health visiting."

*Recent Methods of Treatment.*—Symptomatic treatment, while often affording relief, cannot cure. Even "specific" treatment aiming at the production of immunity, while helpful in certain patients, has proved disappointing. Tuberculin, in its various forms, is no longer regarded as "a cure in the strict sense of the

term" and is not entirely free from risk. The natural power of the human body to amplify its powers of resistance is very great and many cases do well if placed under favourable conditions of life. In this lies the secret of "sanatorium treatment" in which the mode of life of the patient is carefully adjusted to the limits imposed by his disease. Within these limits he can exercise and work with benefit to himself and an increase in the amplitude of his resistance. For the more favourable types of pulmonary cases, sanatorium treatment offers a very definite prospect of restoration to average health and working capacity. Although so much stress is laid on controlled exercise and work, the basis of the treatment is *rest*. In the case of "surgical tuberculosis," too, where the bones and joints of the body are affected, we find in rest the greatest of all adjuvants to recovery. A study of the results attained at such English centres as the Treloar Hospital for Cripples at Alton, the Shropshire Orthopaedic Hospital, the North Wales Sanatorium and the Metropolitan Asylums' Board Hospital at Carshalton will suffice to prove the curability of surgical tuberculosis in children by judicious immobilisation and rest. Fresh air (*see PUBLIC HEALTH*), sunlight (*see HELIOTHERAPEUTICS*) and the artificial sunlight produced by arc lamps are being used, more and more, to help on the results of treatment by surgical rest, and wonderfully favourable results are already claimed for these methods.

In pulmonary tuberculosis, too, the method of "surgical rest" for the affected part is applicable where the disease is confined or almost confined to one lung; and new vistas are being opened up through the use of artificial pneumothorax apicectomy and thoracoplasty. Nothing is more certain than that the surgical treatment of pulmonary tuberculosis is destined to play an increasingly beneficent part in the future. But, while all these methods are of proven value in appropriate cases, none of them can be claimed as a cure, and it is to Chemotherapy that we turn in our hope for the future.

Robert Koch found that salts of certain metals, and especially gold, had a lethal effect on the tubercle bacillus but only in concentrations which were also deleterious to the tissues. Research however, has continued on these lines, and within the last two years, Prof. Möllgaard of Copenhagen has succeeded in producing a gold compound, sodium aurothiosulphate or Sanocrysin, which, while still under test, appears to have a definitely lethal effect on tubercle bacilli in the human or animal body, in concentrations which are non-toxic for the patient. Here, again, we appear to be upon the threshold of a great advance in the treatment of tuberculosis.

**Tuberculosis Schemes.**—Up to the end of 1910, the work of fighting tuberculosis in Great Britain was left, for the most part, to the initiative of the more progressive local authorities, supplemented by private enterprise and the work of voluntary organisations. Much knowledge was accumulated through the work of the Royal Commissions of 1890 and 1901 and through the activities of the Local Government Board, but there was no co-ordinated national effort to deal with the disease.

In Nov. 1911, it was made incumbent on every medical practitioner attending on or called to visit any person suffering from pulmonary tuberculosis to notify the case immediately to the Medical Officer of Health concerned. These regulations, the outgrowth of orders by the Local Government Board of Dec. 1908, were made applicable to *all forms* of tuberculosis in Dec. 1912.

In 1911, too, the National Insurance Act made provision for sanatorium benefit for insured persons, the Local Government Board being empowered to authorise County Councils to provide, maintain and manage institutions for the treatment of tuberculosis. Under the Finance Act, 1911, and the Insurance Act, a sum of £1,500,000 became available for provision of or grants in aid toward sanatoria and other tuberculosis institutions while the Govt. undertook to pay 50% of the annual cost of the anti-tuberculosis work carried out by local authorities. The Public Health (Tuberculosis) Act of 1921 placed a statutory obligation on each County and County Borough Council to make arrangements for the treatment of all persons suffering from tuberculosis, whether insured or not.

Finally, in 1911, a Departmental Committee, presided over by Major (now Lord) Astor, was appointed to report on the general policy in regard to tuberculosis in its preventive, curative and other aspects. The tuberculosis schemes now operative everywhere throughout England, Scotland and Wales are based, for the most part, on the report of the Departmental Committee.

The units in a complete scheme are as follows:—

1. **The Tuberculosis Dispensary or Institute.**—The functions of this unit are to be "a receiving and clearing-house and a centre for diagnosis, consultation and observation, where persons can avail themselves of the services of specially qualified medical men." On the dispensary or institute is based, too, the work of the tuberculosis nurses and visitors, "who advise and instruct patients in a hygienic mode of life" and help the tuberculosis officer to keep in touch with the homes of tuberculous cases.

2. **Residential Institutions.**—These consist of sanatoria for the more favourable cases and hospitals for those patients unable, at the moment, to benefit by sanatorium treatment. The schemes, include arrangements for home nursing, dental treatment, provision of extra nourishment, training in new occupations and "after-care."

The growth of anti-tuberculosis work in England since the passing of the Insurance Act may be gathered from the steady increase in expenditure shown in the following table which is quoted from Dr. Coutts' pamphlet:—

TABLE II. *Tuberculosis Expenditure (England)*

| Period                         | Gross Expenditure of Local Authorities | Income from Insurance Committees | Payments from the Exchequer in aid of Expenditure incurred during the Period mentioned in col. 1 |
|--------------------------------|----------------------------------------|----------------------------------|--------------------------------------------------------------------------------------------------|
| (1)                            | (2)                                    | (3)                              | (4)                                                                                              |
| July 15 1912, to March 31 1913 | 96,000                                 | 34,000                           | 30,000                                                                                           |
| Year ended March 31 1914       | 373,000                                | 189,000                          | 87,000                                                                                           |
| Year ended March 31 1915       | 595,000                                | 227,000                          | 176,000                                                                                          |
| Year ended March 31 1916       | 700,000                                | 211,000                          | 237,000                                                                                          |
| Year ended March 31 1917       | 894,000                                | 251,000                          | 300,000                                                                                          |
| Year ended March 31 1918       | 1,087,000                              | 266,000                          | 384,000                                                                                          |
| Year ended March 31 1919       | 1,285,000                              | 314,000                          | 450,000                                                                                          |
| Year ended March 31 1920       | 1,954,000                              | 621,000                          | 635,000                                                                                          |
| Year ended March 31 1921       | 2,950,000                              | 828,000                          | 1,011,000                                                                                        |
| Year ended March 31 1922       | 3,074,000                              | 200,000                          | 1,717,000                                                                                        |

Large as these figures may seem, there is still a vast field to cover if tuberculosis is to be dealt with adequately on the present lines. The actual notifications, amounting for England and Wales to 57,737 persons in 1924, or 1.47 per 1,000 of population, are admittedly an under-estimate of the known cases, while the undiagnosed carriers of infection must be more numerous still. If the isolation of infective persons is to become effective—and the Public Health Act, 1925, contains clauses providing for the compulsory hospitalisation of infective cases—it will be necessary to face the public maintenance of their dependants while patients remain in residential institutions. And there is an urgent need for further expenditure to provide accommodation and treatment for cases of surgical tuberculosis. The best chance of ultimate economy would seem to lie in the endowment of research directed towards effective preventive measures and curative treatment.

## II. IN THE UNITED STATES

A more or less continuous decline in mortality from tuberculosis had been noticeable in the United States since about 1880; but between 1910 and 1924, and especially after 1917, the decline was extraordinary. The death-rate for the disease fell from 202 per 100,000 population in 1900 to 160 in 1910; 150 in 1917; 91 in 1924; a reduction of 55% for approximately the first quarter of the century, and of 21% for the first decade, only 6% from 1910 to 1917, and 39% between 1917 and 1924. Although the statistics have not yet been compiled it is estimated that the tuberculosis mortality for 1925 will show a further decline, to about 88 per 100,000. Such a diminution of mortality in a disease like tuberculosis is unparalleled in the annals of epidemiology. In 1915 tuberculosis, which had always been the first cause of death, yielded its unenviable pre-eminence to heart disease. It has since been outranked also by pneumonia, cerebral haemorrhage (apoplexy), and cancer, so that in 1924 it occupied fifth place or near the foot of the list of major diseases. As usual, pulmonary tuberculosis accounted for about seven-eighths of all deaths due to the disease.

*Urban Communities.*—All sections of the country and all elements of its population participated in the great betterment. But urban communities, as exemplified in New York City, outstripped the rural districts in the control of the disease. In them tuberculosis is declining more rapidly than in the country at large. In 1900 New York City's tuberculosis death-rate was 280, or 39% higher than that for the nation; by 1920 it had fallen to 126, or only 11% greater; and in 1924 it was 93, or barely 2% in excess of the general rate. Such changes are revolutionary and, for a great and crowded city, are unparalleled in the history of tuberculosis. They may be better appreciated by reference to the accompanying chart, which suggests that in 1924 a New York citizen's chance of dying of tuberculosis was less than one-half that in 1910 and one-third that in 1900. Among infants and children the reduction of tuberculosis has been almost sensational. In New York City the death-rate for infants in 1923 was only one-sixth that of 1898 (94 in 1923 and 609 in 1898), while for children under 15 the decline between the two years was from 136 to 33.

*Causes of Decline.*—Much has been written about the causes of the continued, and of late the extraordinary, decline of the disease. The phenomenon is apparent in all countries under our industrial type of civilisation, although latterly it has been most marked in the United States. The presumption is therefore strong that broad economic and social movements which characterise our era, though they elude close definition, are potent factors. Undoubtedly, the amelioration of existence, a resultant of the enormous increase of wealth in the United States, has played its part. But two other instruments have also been brought to such effectiveness in that country as to be likewise decisive in the control of tuberculosis.

*Organisation of Control.*—The first is the National Tuberculosis Assn., founded in 1904. Through its central office in New York City and its hundred and more subsidiary state and civic bodies, this organisation extends its influence into every hamlet, as it maintains services and agencies to be applied to every phase of the disease. Its funds are recruited through the unique manner of selling, every year at Christmas-time, its so-called "Christmas seals" stamps to be affixed to postal matter but not for postage. Their sale has become so enormous as to bring an annual gross return of almost \$5,000,000 though they cost but a cent each.

*Sanatoria.*—As organisation is the key-note of the social control of the disease, so is the sanatorium the keynote of its medical control. In no other country has the sanatorium movement been so highly developed. Twenty years ago, when death-rates were around 200, there were hardly a score of these institutions in the United States. In 1925 they numbered more than 600, with a capacity of 52,460 beds for civilian patients and 13,940 beds for Federal patients, veterans of the wars. Their annual "turn-over" was approximately 150,000 patients, or perhaps one-fifth of those ill with the disease. The standard of institutional facilities has been put at one bed for every annual death. On this

basis the United States, with 78,096 deaths from pulmonary tuberculosis in 1924 (Registration Area), has perhaps two-thirds the ideal equipment, omitting the beds for Federal patients.

*Special Treatment.*—Of special methods of treatment, artificial pneumothorax (*q.v.*) has become a standard procedure, much employed in selected pulmonary cases. Since 1920, more radical surgical measures, such as the various forms of thoracoplasty, have been on trial; their use is increasing rapidly. Heliotherapy (*q.v.*), sun treatment and other forms of light therapy are now in common use in non-pulmonary disease. Specific treatment (tuberculin) valuable only in expert hands, holds its own. Chemotherapy has made no headway; nor have the various preparations, advocated recently on the continent of Europe (*Sanocrysin*, *Krysolgan*, etc.) been, as yet, received kindly in the United States. Of all diagnostic measures, the X-ray (*q.v.*) has had by far the greatest development, and has become indispensable. It has not, of course, superseded physical examination; and it is noteworthy that time brings a growing appreciation; that diagnostic precision and refinement are to be attained only through the co-operation of the examining physician and the Röntgenologist. No specific or laboratory test has been found decisive in diagnosis, except the long-recognised demonstration of tubercle bacilli in tissue products.

*Immunity.*—The practitioner of 1925 regarded tuberculosis from a point of view quite different from that of 1910. The disclosure that tuberculosis exists as a latent infection in almost all people, and that infection confers a measure of specific immunity to reinfection, gave rise to the almost necessary presumption that adult pulmonary tuberculosis develops from infection acquired in childhood and that the adult is insusceptible to exposure to infection from without. But latterly an increasing number of studies of American authorities has brought about some modification of too rigid an adherence to this opinion. They have shown that conditions are only relative. Although early infection and a resulting immunity are conceded, it is pointed out that infection is capable of complete healing, with a consequent great diminution or even disappearance of immunity; and that, therefore, there is every likelihood that reinfections—and active disease from them—are possible at almost any period of life.

In 1915 there occurred the death of Edward L. Trudeau, the recognised pioneer and leader of tuberculosis activities in the United States. In the next year was held the first session of the Trudeau School of Tuberculosis, the first of its kind, in Saranac Lake, N.Y., to give systematic instruction to physicians. In 1917 was issued *The American Review of Tuberculosis*, a monthly scientific periodical, founded by the *National Tuberculosis Association*. It was in 1925 the only tuberculosis journal in the United States, and had done much to stimulate the study and investigation of the subject. Among the more prominent centres of research in tuberculosis were the Trudeau Foundation at Saranac Lake, the Henry Phipps Institute at Philadelphia, the Kenneth Dows Laboratories of Johns Hopkins University at Baltimore, the National Jewish Hospital for Consumptives at Denver, the Municipal Sanitarium in Chicago and the Colorado Foundation at Colorado Springs, all of which were established since 1910. (A. K. K.)

**TUKHACHEVSKY, MIKHAIL** (1893– ), Russian soldier, was born in the government of Smolensk. He received the best Russian military education in the corps of cadets and the Aleksandrovsky military school, out of which he passed in July 1914. In Feb. 1915 he was taken prisoner by the Germans, and, after several fruitless attempts to escape, he succeeded in the autumn of 1917 and made his way back to Russia. He was at once taken into the military service of the Soviet, took part in the operations in defence of Petrograd (Leningrad), and in June 1918 received the command of an army. He commanded successively the I., VIII. and V. Armies and then the Caucasian front. After the successful conclusion of operations against Denikin, Tukhachevsky was given the command of the Western front. After the Civil War he became chief of the military academy, and in April 1924 was appointed assistant chief-of-staff.

**TULSA**, Okla., U.S.A. (see 27.368), in the midst of the rich, oil-producing area of northeastern Oklahoma, increased fourfold in population in the 10 years after 1910, reaching 72,075 in 1920 (109.3 males to 100 females), of whom 8,878 were negroes and only 2,025 foreign-born. In 1925 the census bureau estimate was 124,478. Annexations of land brought the area to 12 sq. m. in 1925.

In 1925 there were 1,500 individual firms engaged in the oil business. The International Petroleum Exposition was established in 1923, on its permanent ground of 10 acres. Manufactures developed rapidly, until in 1923 there were 106 establishments producing goods valued at \$22,327,907. Debts to individual accounts in Tulsa banks amounted to \$1,181,952,000 in 1923. Civic improvements, up to 1925, included the adoption of a town plan, a regional plan and zoning regulations; the extension of the park system until there were 13 larger parks, containing 2,385 ac., and numerous small playgrounds; and the completion of a water-supply system at a cost of \$8,000,000 which brings soft Ozark Mountain water from a reservoir of 20 billion gal. capacity in the Spavinaw Hills, 60 m. distant, over and under rivers, hills and ravines, by force of gravity alone, although the difference in the elevation of the source and the terminus is only 90 feet. In June 1921 there was a serious race riot, in which more than 25 persons lost their lives and many more were injured. As a consequence, the county was placed under martial law by the governor for a time in 1923. The old council tree of the Creeks, a huge spreading elm, still stood (1926) in the grounds of a private residence.

**TUNISIA** (see 27.393), area about 50,000 sq. m.; population (1921) 2,093,939. The natives numbered 1,937,824, of whom 48,436 were Jews. The Europeans numbered 156,115 and included 54,476 French, 84,799 Italians and 13,520 Maltese. Tunis, the capital, had 171,672 inhabitants, Sfax 19,754 and Bizerta 20,763.

**History.**—The protectorate form of government was maintained, the Bey being the head of the Regency, while the French resident-general controlled the administration, the army of occupation being 25,000 strong. Mohammed en Nasr, who had been Bey since 1906, died in 1922, and was succeeded by his cousin Mohammed el Habib (born 1858). During the World War tribesmen from Fezzara, led by Turkish officers, attacked the French outposts in southern Tunisia. There was some sharp fighting in Sept. and Oct. 1915, when the French re-established order. Later on large numbers of Tunisian soldiers were employed in France. In 1919–20 by agreement with Italy the territory on the Sahara south of Tunisia forming salients between the oases of Ghadames and Ghat and between Ghat and Tummo was transferred by France to Tripolitania.

As the census figures given show, the majority of the European inhabitants are Italians or Maltese. As part of an effort to give the protectorate a more French character, decrees were issued in 1921 declaring that British (*i.e.*, Maltese) and Italian subjects, born of parents who were themselves born in Tunisia, would be deemed to be of French nationality. These decrees provoked resentment, especially among the Italians, whose right to maintain their nationality was protected by a convention of 1896 still provisionally in force, and no settlement of the question with Italy had been reached by 1926. As to the British, an arrangement was reached with France in 1923 whereby the persons affected were entitled to decline French nationality.

In 1922, in order to give Tunisians a larger share in the administration, a general council for the protectorate, consisting of 44 French and 18 nominated native representatives, and also regional councils, were established. The general council superseded the consulting conference set up in 1905, and had greater powers than that body. There had already arisen a nationalist agitation, and this in 1924–5, when the cost of living was four times as great as in 1914, was mixed up with a Communist agitation accompanied by some disturbances in the towns. The Communist agitation was not deep rooted, but among educated Tunisians there was a demand for a democratic form of government. This demand was not met, but as an educational measure

further powers were conferred in 1925 on municipal councils." In archaeology important excavations were carried out at Carthage and other sites, and efforts were made to attract tourists.

**Industry and Trade.**—Tunisia is essentially an agricultural country, but has also very valuable mineral resources. The average annual export of wheat in the period 1915–24 was 319,000 quintals, of barley 627,000 quintals. Tunisian olive oil is of very high quality; there were in 1924 8,000,000 fruit-bearing olive trees, and the production of oil was 220,000 quintals. Tunisian wines, mostly red, are of some repute, and some 600,000 to 800,000 hectolitres are produced yearly. Of minerals the production of phosphates was 1,882,000 tons in 1912, had fallen to 819,000 tons in 1918, and had risen to 2,400,000 tons in 1924. Iron, lead, zinc and manganese ores are also exported in considerable quantities. Marine salt of a superior quality is produced to the extent of some 300,000 tons annually—it is exported to places as far apart as India and the United States.

In 1913 imports were valued at 144,000,000 fr. and exports at 185,000,000 fr.; for 1924 the figures were imports 927,940,000 fr., exports 582,350,000 francs. The Tunisian franc follows faithfully the movements of French currency, so that no exact comparison can be drawn between the figures of 1917 and 1924. More satisfactory evidence of prosperity was found in the increased production, while the excess of imports was due to the comparatively rapid development of the country's resources—only a small part of the imports were for articles of luxury. External trade was increasingly with France, the combined result of a protective tariff and the low exchange value and instability of the franc. Next to France trade is chiefly with Italy, Great Britain and the United States. The British trade was in 1924 some 17% of the total.

Considerable sums were spent, from the raising of loans, on railways, agriculture and colonisation by French settlers. The budget figures of 1924, for ordinary receipts and expenditure, showed a surplus of 40,413 fr. on a total revenue of 219,130,800 francs. In 1915 (with the franc at par) revenue had been 60,000,000 fr. and the surplus 1,470,000 francs.

**TUPPER, SIR CHARLES** (1821–1915), Canadian statesman (see 27.410), died Oct. 30 1915.

**TURBINE, STEAM** (see 25.823 and 842; also STEAM ENGINE). **The Reaction and Impulse Principles.**—Since the kinetic energy in a jet of steam issuing from a nozzle resides entirely in the velocity of the steam, it follows that to utilise the energy efficiently the steam must be brought as nearly as possible to rest. There are two methods by which this can be accomplished. Either the nozzle itself may be caused to move backwards with such a velocity that the issuing jet of steam remains stationary in space or on the other hand the jet of steam may be made to impinge on a moving blade system and its velocity thus abstracted. The words "reaction" and "impulse" are used respectively to designate the two principles outlined, and the same terms have now come into general use as descriptive of turbines which embody, more or less, the respective principles.

The development of the steam turbine as a practical machine dates from 1884 when Sir Charles Parsons patented a design in which the total range of steam pressure which it was desired to utilise was divided up into a large number of stages, the small velocity energy due to each partial drop of pressure being absorbed before the next partial drop occurred. The complete turbine thus consisted of a number of elementary turbines working in series, each of which, having only a small steam velocity to deal with, could operate efficiently with quite a low blade speed. The Parsons principle of "pressure compounding" a turbine in this manner can be taken advantage of in two ways. If each partial pressure drop takes place in a set of fixed nozzles,

so that steam at the full velocity due to this drop impinges on the running blades, we have what is known as the pressure compounded "impulse" turbine. If, on the other hand, the steam is arranged to expand in both the fixed and running elements of the turbine, so that the moving blades are impelled chiefly by the reaction of the steam issuing from them, the machine is called a pressure compounded "reaction" turbine.<sup>1</sup>

#### VARIOUS TYPES OF TURBINE

*The Parsons.*—The inherently high efficiency of the reaction water turbine was well known to engineers prior to 1883, and for this reason the original compound steam turbine of Sir Charles Parsons was constructed as a "reaction" machine. The reaction principle as developed by him at Heaton Works, Newcastle-on-Tyne, has since been embodied in turbines aggregating millions of horsepower and is the principle employed in many of the largest and most efficient plants in the world. The first Parsons turbine was constructed in 1884-5. It consisted of a rotor about 3 in. in diameter carrying numerous rings of outwardly projecting brass blades which alternated with corresponding rings of fixed blades projecting inwards from the casing. Steam was admitted at the centre of the casing and flowed axially to the exhaust at each end. The partial expansion of the steam in each row of the fixed blading generated a velocity which was absorbed by the succeeding row of moving blades, while the similar partial expansion of the steam in the latter tended to urge them forward by its reactive effect. The action of the steam was identical with that employed in the reaction turbine as built to-day. This early machine was directly coupled to a 4 kw. Parsons dynamo which it drove at a speed of 18,000 revolutions per minute. It used steam at a pressure of 60 lb. per sq. in., and exhausted to atmosphere, its steam consumption under such conditions being about 200 lb. per kw. hour. It worked satisfactorily for several years, and, owing to its historic value as the prototype of the modern steam turbine, has since been placed in the South Kensington Museum (see fig. 1 on plate).

*The De Laval.*—In the year 1887 De Laval patented an improved impulse turbine, the essential feature of which was the employment of a diverging nozzle to develop the velocity due to the full pressure drop of the steam and to direct the latter on to the blades of a single wheel. The invention of the diverging nozzle was a highly important one in connection with impulse turbines, as without it only a small range of expansion could be efficiently utilised. Since in the De Laval turbine the whole of the energy of the steam was to be absorbed in a single stage, very high blade speeds were necessary, and these implied very high speeds of rotation. The wheel was of special design to withstand the severe centrifugal stresses involved and it was mounted on a very thin flexible shaft in order that it might be able to rotate about its own centre of gravity and principal axis when running. The wheel of a 5 H.P. turbine had a diameter to the centre of the blades of only 3.94 in., and ran at no less than 30,000 revolutions per minute. In a machine of 300 H.P. the wheel was 29.92 in. in diameter and made 10,600 r.p.m., giving a mean blade speed of 1,380 ft. per second. At such speeds of revolution direct driving was impossible, so De Laval incorporated double-helical gear in the design, giving a speed reduction ratio of about ten to one. Owing to greater limitations to permissible stresses in larger disks and to the difficulty of providing sufficient nozzle area round the wheel, turbines of this type have not been constructed in sizes developing more than a few hundred H.P., but within their limitations they are moderately efficient machines. By the invention of the diverging nozzle and high-speed mechanical gearing, De Laval made two important contributions to turbine development.

*The Compound Impulse.*—The typical impulse turbine of to-day owes its development principally to Prof. A. Rateau of Paris, whose work on steam turbines dates from 1894, when he first devoted his attention to simple impulse machines of the de Laval type. The essential feature of the modern Rateau

turbine is the use of a succession of simple De Laval impulse wheels in series in the steam flow, *i.e.*, compounded on the Parsons principle of subdivided pressure drop, already described. All subsequent designers of successful impulse turbines have followed the lines laid down by Rateau; except as regards certain minor details of construction. Modern machines of the compound impulse type have been constructed in sizes up to 60,000 kw. capacity, and high efficiencies have been obtained.

A feature that is peculiar to impulse turbines is the ease with which the admission of steam may be restricted to a part only of the circumference of the bladed wheels, by admitting steam through nozzle groups subtending only a small arc. It is now recognised that this results in a certain loss of efficiency due to the fan-action of the unoccupied blades, but on the other hand it permits the substantial advantage of using blades of a reasonably large height running at an adequate velocity at the high pressure end of the turbine, where the volume of steam to be passed through the nozzles and blading is but small. Another special feature of the impulse turbine is that, since the steam can be expanded in the nozzles to a moderate pressure before entering the body of the machine, no part of the main casing or of the wheels or blading system need be exposed to steam at the initial high pressure or temperature. The losses due to disk friction of the wheels running at high speeds in a comparatively dense medium, and those due to the comparatively high velocity of the steam through the blades, are however considerable.

*The Curtis.*—The essential feature of the Curtis turbine was the combination of the expanding nozzle of De Laval with "Velocity compounded" blading. The steam entered the blading of each stage at a comparatively high velocity, acting on a wheel carrying two or more rows of blades, alternating with fixed blades projecting from the casing. After acting on the first row of moving blades it was deflected back on to the second row by the fixed, or "guide" blades and so on, its velocity being continuously reduced. As many as four moving rows per wheel were adopted in some instances, and thus a high initial steam velocity could be dealt with by blading running at a very moderate speed. It is, however, very difficult to obtain a satisfactory efficiency with several rows of impulse blades working in series in this fashion, and the use of two rows only per pressure stage became general.

*The Ljungström.*—This is a compound reaction machine in which the alternate rows of blading are arranged to project axially from opposed discs which rotate in opposite directions. Each disc is mounted on the end of a separate shaft carrying an alternate rotor, the two alternators working electrically in parallel and each contributing half the total output of the machine. The steam is introduced between the centres of the bladed discs and flows radially outwards, escaping at their circumference to a space connected with the condenser. Since both blade systems rotate, the relative blade speed is double that which would correspond to the speed of rotation at which each of the alternators is driven, consequently the required degree of pressure compounding can be obtained with a reduced number of blade rings. The similarity of the discs and the method by which the blade rings are fixed, moreover, practically eliminate difficulties due to distortion when running, and very fine clearances can therefore be used.

*Combined Types.*—The velocity compounded wheel of Curtis is frequently used for the first pressure stage of a turbine of which the succeeding stages are either of the reaction or of the simple impulse type. The builders of compound impulse machines frequently seek higher efficiency by arranging for a certain amount of expansion of the steam in passing through the blading, thus partially adopting the reaction principle. The construction of turbines consisting of a multi-stage pressure-compounded high-pressure cylinder, followed by a low-pressure cylinder of the reaction type has been advocated and several such machines have been built. The idea of constructing a turbine in more than one cylinder is not new, having been first adopted by Parsons in the 2,000 s.h.p. turbine engines of the steam yacht.

<sup>1</sup> Throughout this article the value of one kilowatt is understood to equal 1.34 horsepower.

Parsons Reaction Steam Turbo Alternator, arranged Cross Compound on 3 shafts (I.P. and L.P. in line). Speeds, H.P. and I.P. 1,800 r.p.m. L.P. 720 r.p.m.

"Turbinia" in 1879 and in the 1,000 kw. turbines constructed for Elberfeld so long ago as 1900. In the combined type referred to, the impulse portion contains an unusually large number of wheels, which are of comparatively small diameter and turned from a solid forging. The blade speeds and steam speeds are therefore low and the disk friction is also less than would be the case with larger wheels.

#### PRESENT POSITION OF THE TURBINE

So rapid has been the development of steam turbines since the construction of the first turbine of 10 H.P. in 1884 that their position as prime movers for the generation of electrical energy and many other purposes is now unrivalled. The successful development by Parsons of double-helical gearing for the transmission of large powers has permitted complete freedom of choice with regard to turbine speeds, so that the steam turbine, which is essentially a high-speed prime mover, can be employed with advantage for driving machinery which is required to run at any moderate or even low speed. Mechanical gearing has, for example, supplied the solution to the problem of the continuous current turbo-dynamo. Moderate speed generators have now reached an output of 3,000 kw. from a single machine, the current collected from a single commutator being as much as 6,000 amp., and with the interposition of gearing such generators can now be turbine-driven.

Turbines of only a few horsepower are now frequently used to drive fans, centrifugal pumps and auxiliary apparatus used in connection with power stations, and there appears to be almost no limit to the applicability of the turbine as a prime mover. For steam railway locomotives, the reciprocating engine still holds its own, but there are signs that the turbine may also find a place. Progress in this direction has been hindered by the two practical difficulties of reversing the locomotive easily, and of constructing a satisfactory portable condenser. The variable speeds at which locomotives must run also impose a condition adverse to the turbine. Nevertheless the construction of the Reid-Ramsay locomotive in Great Britain, and particularly of the Ljungström locomotive in Sweden, the latter operating in regular service with a fuel consumption only half that of reciprocating-engine locomotives on similar duty, indicates a possible development in this direction (see RAILWAY ENGINEERING; LOCOMOTIVE DESIGN).

*Trend of Modern Design.*—The broad difference in the practices of to-day lies between the so-called impulse and reaction principles as applied to horizontal compound turbines. The arguments in favour of either type may be based either on preference for the mechanical construction appropriate to it, or on the theoretical efficiency to be obtained from it. The cost of manufacture is also an important commercial factor. This last consideration tends to the construction of impulse turbines with comparatively few stages, seven or eight being commonly employed in a medium-size machine. Such machines are short and compact, but the high steam velocities inherent in the design involve serious frictional and eddy losses both in the nozzles and blades. Trouble with erosion of the blades, especially towards the low-pressure end of the turbine where the steam is wet, is also sometimes experienced. The much lower steam velocities, due to the many times more numerous stages which are usual in a reaction turbine are favourable to efficiency. Moreover, since the steam velocities in a pair of fixed and moving blade rows in a reaction turbine are identical, considerations of symmetry would indicate that a higher efficiency would be obtainable than in a turbine in which the whole of the expansion per stage took place in one element (the nozzles). It is interesting to note that builders of reaction machines have experimented with different ratios of expansion in the fixed and moving elements, but up to the present the practice of using equal ratios has proved to be the best. An approach towards the reaction principle has been advocated by some builders of impulse turbines, who consider it better to allow a certain amount of expansion to take place in the moving blades, but opinion is by no means unanimous on this point.

In modern practice the best results as regards blade efficiency are obtained with a ratio of blade speed to steam speed of about 0.85-0.90 in the case of reaction turbines, and 0.43-0.48 in the case of impulse turbines having a single row of rotating blades after each set of nozzles. The diminution of nozzle efficiency with increasing velocity of the steam has been confirmed by recent investigations of the Steam Nozzles Research Committee<sup>1</sup> but there yet remains to be found the exact cause of this loss of efficiency and whether its reduction or elimination is possible. Another point which bears upon steam turbine design is the experimental fact that the stage efficiency of a turbine is less with saturated or wet steam than when the steam is superheated.

*Thermodynamics of Turbine Design.*—These problems are closely associated with the thermodynamics of turbine design. All engineers engaged in such work are desirous of making the design of nozzles and blading a matter of exact calculation, and are also anxious to be able to agree upon a rational basis of comparison for the performances of different turbines working with different steam conditions. Up to the present these problems are not completely solved, the influence of the cumulative heat due to the inefficiency of the several stages of a turbine, and the experimental fact of decreased stage efficiency where wet steam is found, having made exact calculation somewhat difficult.

The proportion of the heat supplied to the steam in the boiler that is converted into useful work, does not depend upon the efficiency of the turbine only, but is a function of the conditions under which the heat is received and rejected. The efficiency of the thermodynamic cycle, which governs the relation between the available energy and the heat supplied to the steam, is explained in the article on thermodynamics (*q.v.*).

Attention has been turned to the possibilities of increasing the available energy itself by extension of the thermodynamic cycle, more particularly in the case of land turbines which operate under much less restrained conditions than those prevailing at sea. By the use of higher pressures and temperatures (see STEAM ENGINE), the lowest possible vacuum and other devices, it is not unreasonable to expect to reach an overall thermal efficiency (from fuel to electricity) of 30% or in other words an efficiency not inferior to the best attained by oil engines, even neglecting the oil consumed in cylinder lubrication.

With regard to the possibility of increasing the thermodynamic efficiency by extending the lower end of the temperature range, which the turbine can utilise to an extent completely beyond the range of the reciprocating engine, a limit is imposed in this direction by the temperature of the cooling water available. A condenser temperature of about 70° F., corresponding to an absolute pressure of 0.36 lb. per sq. in., or a vacuum of 29.25 in. of mercury (barometer 30.00) is about as low as can be maintained in practice under favourable conditions. The effective use of such a vacuum demands, however, the provision of adequate blade area and passage way for the low-pressure steam, which is of great volume. Throughout the stages of a turbine the criterion of efficiency is the ratio between the blade speed and the steam speed, and the areas of the blade passages must successively increase in such a manner as to maintain the desired velocity ratio.

The axial component of the steam velocity is carried on from stage to stage without appreciable loss. It is even built up to higher values as the peripheral and steam velocities increase. Its final loss at the exhaust end of the turbine, however, is practically unavoidable, and with the high peripheral speeds adopted in most low-pressure blading at the present day, an exhaust blade area which gives a perfectly satisfactory velocity ratio may entail a loss of energy in the issuing steam of considerable amount. Such loss is augmented if, for the sake of weight or cost, any sacrifice is made of the final velocity ratios, which sacrifice might otherwise be a perfectly justifiable compromise. It is evident, therefore, that the exhaust end of the turbine requires separate treatment in its design from the point of view of limitation of the

<sup>1</sup> See *Proceedings of the Institution of Mechanical Engineers*, Jan. 1923 et seq.

leaving loss, that is, the energy lost in the issuing steam. Broadly speaking, where high efficiency is the aim, this consideration imposes a limit upon the axial velocity of the steam in the final annulus. For a given vacuum, therefore, the area of the final annulus must increase in proportion to the output, and for a given output any increase in the vacuum involves an increase in the area of the final annulus. It will be seen, therefore, that any effort to extend the steam cycle, by lowering the temperature of condensation, brings at once into prominence the problem of the exhaust end.

Various expedients have been adopted for the purpose of surmounting this limitation. The area of the final annulus can be increased by increasing the blade height, and any means of extending the height permissible on a given diameter is valuable for this purpose. Thus in many turbines, the blades of the last stages are made of varying section and discharge angle, permitting a greater length ratio without unduly increasing the centrifugal stress. Another method, commonly employed in both land and marine turbines, is to carry out the final stages of the expansion by divided flow, as for example in a double ended low-pressure turbine, the steam entering at the middle and flowing in each direction towards an exhaust at each end. In such an arrangement two exhaust pipes are provided and frequently two condensers. In another example of divided flow, some makers double only the last row or last few rows of blading, employing specially shaped passages to conduct the steam to the divided portion from the preceding stages. The design of exhaust end advocated by Baumann is yet another attempt to overcome the same difficulty. In this device instead of carrying over a part of the steam by special ports to additional blade rings, it is made to flow through inner annuli of the preceding blade rings, the vanes of these inner annuli being specially shaped to reduce the resistance involved to a minimum.

If no restrictions are imposed, either upon the diameter of the exhaust end or upon the speed of revolution, a simple and probably the best solution of the exhaust area problem in large machines is to provide a separate low-speed turbine of large diameter for the final stages of the expansion, having blades of normal profile throughout, and correspondingly high efficiency. This low-speed turbine can be arranged in close proximity to the condenser, so as to reduce to a minimum both the length and the resistance of the exhaust passages.

In the exhaust passage itself, it is not sufficient to provide area to reduce the mean velocity of the steam passing through it to a moderate value, but the exhaust steam must be distributed into the passages uniformly, so that the velocity is everywhere nearly the same. Neglect of this requirement leads to unnecessary hydraulic losses, and may also cause troublesome blade vibration in the final stages.

Many attempts have been made to obtain the benefit of the diffuser principle, which has been so commonly adopted in the case of water turbines, but in the case of steam turbines without substantial success. In any attempt to carry this principle into effect, ample exhaust pipe area should be provided, with progressively larger cross section on the way to the condenser, so that the exhaust steam from the last row of revolving blades is gradually slowed down, with a possible recovery of static head. The practical difficulties in the way of such recovery of pressure in the exhaust steam are very great, and the best that can be done in this direction would appear to be to utilise the leaving velocity of the exhaust steam to overcome the resistance to flow in the exhaust passages, so that the absolute pressure at entry to the condenser is the same as at the exit from the blading.

Modern practice with regard to these matters may, perhaps, be best exemplified by the large Parsons turbine plant (see fig. 3 on plate) erected (1925) in the new Crawford avenue power station at Chicago, where, after allowing about 3% for the total power absorbed by the auxiliaries, an overall thermal efficiency (from fuel to electricity) of 27.80% is anticipated.<sup>1</sup>

*Developments in Marine Turbines.*—The design of the earlier marine turbine installations was largely a matter of compromise

between the high speed of revolution desired for the turbine and the much lower speed which was more suitable for the propeller. Like all compromises, each side had to sacrifice something and although a satisfactory efficiency could be obtained in the case of high-speed vessels, it was realised that a much greater economy would be possible if both turbine and propeller could be arranged to run each at its own most efficient speed of rotation. This was of course impossible so long as both were directly coupled together. By the introduction of gearing between the turbine and the propeller, the desired freedom of each with regard to speed was obtained, and thus the turbine not only became applicable to slow-speed vessels, but better results were obtainable even in high-speed vessels, such as warships, liners and channel boats where the direct coupled drive was already firmly established.

A small example of marine turbine reduction gearing had actually been built in 1897, in connection with a twin-screw launch in which the Parsons Marine Steam Turbine Co. fitted a 10 H.P. turbine driving the two shafts by means of helical gearing with a speed ratio of 14:1. In 1909 the "Vespasian," a cargo vessel of 4,350 tons displacement, was fitted with geared turbines driving a single propeller. The vessel had previously been equipped with triple expansion reciprocating engines of the usual type and before these were removed they were put into perfect order and very careful tests were made to determine their efficiency and performance. The geared turbines drove the same shaft and propeller as the engines had done and were supplied with steam from the same boilers. The power developed was about 1,000 H.P. and the shaft ran at 70 revs., the gear ratio being 19.9:1 in a single reduction. The installation of the turbines resulted in an increase of about one knot in speed for the same coal consumption, or alternatively a saving of 16% in fuel consumption, and the results of the trials were convincing as to the advantages of geared turbines over reciprocating engines. After the "Vespasian" had run 18,000 m. in regular service, the pinion was examined and found to be in perfect condition, the wear not exceeding 0.002 inches. (See *Trans. I.N.A.*, 1910 and 1911.)

The success of the "Vespasian" led to rapid developments. In 1910 the British Admiralty introduced mechanical gearing, the torpedo boats "Badger" and "Beaver" being the first warships to be fitted with geared turbines. In these vessels each L.P. turbine drove its shaft directly but the H.P. and cruising turbines were geared to a forward extension of the L.P. turbine rotor. At full load about 3,000 H.P. were transmitted through each set of gearing. Six years later complete gear drives had become the standard practice for British war vessels of all types and by 1920 some 650 gears, transmitting an aggregate of 7,280,000 H.P., were fitted or on order for the Royal Navy (Tos-evin, *Trans. I.N.A.*, 1920).

Numerous tests have been carried out to determine the mechanical efficiency of large marine turbine reduction gears. The efficiency of a single reduction gear at full load should be over 98%, and efficiencies of 98.5% have been recorded. With double reduction gear the efficiency is over 97%. These figures include bearing friction. No method of obtaining speed reduction by hydraulic or electrical methods has yet been devised which has approached the efficiency obtainable with mechanical gearing.

Since the introduction of mechanical gearing the marine turbine has tended to become assimilated in type to the land turbine, the same conditions making for thermal efficiency, namely, high velocity ratios, high steam pressures and temperatures and high vacua, being equally applicable. An arrangement of turbines in which the high pressure portion of the expansion is confined to a small high-speed turbine, is advantageous for the improved thermodynamic systems already referred to in connection with land practice, and such systems with high boiler pressure and temperature are now on the point of being introduced into marine work.

Assuming such a design to be adopted for an installation of about 5,000 s.h.p. with boiler pressure 500 lb., maximum temperature 700° F., feed heating to 350° F., and effective air pre-heating to give a boiler efficiency of about 84%, a careful estimate based

<sup>1</sup> For a full account of this plant see *Engineering*, vol. 121, p. 283.

on known performance shows that, owing to the increased available energy of the steam and when burning oil, a fuel consumption of about 0.55 lb. per s.h.p. would be obtained for turbines only and about 0.65 lb. per s.h.p. for all purposes including auxiliary machinery.

An installation on such lines is now under construction for a Clyde steamer which will therefore be the pioneer of this improved method of propulsion. The machinery will have a propulsive s.h.p. of 3,500 on two shafts with a boiler pressure of 550 lb. per sq. in. and a temperature of 750° Fahrenheit. The principle of stage feed heating is to be adopted. The feedwater will first be heated to about 200° F. by the auxiliary exhaust steam and then raised to a higher temperature in a second heater by steam withdrawn from the turbines. The boilers will be coal-fired and the air to the furnaces heated by the flue gases by means of air preheaters arranged in the uptakes. It is anticipated that this installation will satisfactorily demonstrate the practicality of applying the latest land practice to marine work and will pave the way to a considerable advance in economy in marine propulsion.

Two examples of such applications, for total outputs of 27,000 and 13,500 S.H.P., were described in a paper read by Sir John Biles,<sup>1</sup> and comparisons made on an economical basis with installations of other types for the same vessels with Diesel engines. When the difference in price between fuel oil and Diesel oil is taken into consideration and also allowance made for the cost of lubricating oil for the Diesel engines in excess of that for turbine, such proposals promise an economy in cost of fuel not inferior to that obtained with Diesel engines, whilst they permit the use of either coal or oil as fuel. Further the first cost of such an installation will be considerably less than the cost of Diesel engines and little, if any, greater than that of a geared turbine installation of the usual design with low pressures and moderate superheat.

**TURIN**, Italy (see 27.418), the fourth city of Italy, and the chief town of Piedmont, is a flourishing and important industrial centre, with a population in 1921 of 502,274 (517,140 including suburbs). The city has large motor car and artificial silk industries. A fine monument to Mazzini was erected in 1915 at the junction of the Via Pomba and the Via Andrea Doria, and a memorial to Italian cavalrymen to the east of the Palazzo Madama in 1923.

**TURKESTAN** or **TURKISTAN** (see 27.419), the name applied to certain Russian territories just east of the Caspian. Russian Turkestan is divided between two independent Socialist Soviet republics, Turkmenistan and Uzbekistan, which, however, are constituent states of the U.S.S.R. Turkmenistan (capital Polterask, formerly called Askabad, with a population of 33,636 in 1925) comprises all the territories west of the Oxus and the south of the Kirghiz A.S.S.R., and also a small strip of territory on the east bank of the river. Uzbekistan (capital Samarkand,

with a population in 1925 of 72,370; largest town Tashkent, with population of 263,871), comprises the territory between the Oxus on the south, where it forms the Afghan frontier, Turkmenistan on the west, the Kirghiz A.S.S.R. on the north and the Kara Kirghiz autonomous province on the east. It includes nearly the whole of Bokhara, and the districts of Ferghana and Samarkand. Comprised within its territory is the autonomous Socialist Soviet Republic of Tadjikistan (capital Durhambe), which forms the southeastern portion of Uzbekistan. These administrative divisions correspond fairly accurately with the ethnographical distribution—the three republics being inhabited principally by Turcomans, Uzbeks and Tadjiks respectively. According to estimates of 1925, Turkmenistan had a population of 914,558, of which 79% were Turcomans and 5% Russians. Its exact boundaries had not been delimited. Uzbekistan had a population of 4,150,000, of which 3,575,000 were Uzbeks, and an area of 184,800 sq. miles (250,000 versts). Tadjikistan had a population of 609,000, of which 90% were Tadjiks, and an area of 31,680 square miles.

**Political History.**—After the revolution of March 1917 the Amir of Bokhara asserted his independence and on April 20 granted a constitution; while the Provisional Govt. of Russia convened an All-Russian Moslem congress in May 1917, which was eventually dissolved by the Bolsheviks in May 1918. It appears to have achieved little. Following the Bolshevik revolution, a Turkestan Moslem congress proclaimed, in Dec. 1917, the autonomy of Turkestan and Khokand, and established a Provisional Govt., which, however, was overthrown by the Bolsheviks in Feb. 1918. By May the Bolshevik forces had surrounded Bokhara, and in August they had established themselves in Merv. In November "White" forces recaptured Merv, only to lose it the following May, after which event a Turkestan Soviet Govt. was formed, which in August sent a diplomatic representative to Kabul. In Sept. 1919 there was a successful anti-Bolshevik rising in Ferghana, which resulted in the formation of a Provisional Govt., which lasted until Feb. 1920. This month saw the consolidation of Soviet power in Turkestan; a rising in Khiva resulted in the abdication of the Khan, and by the end of the month only Bokhara maintained a precarious independence under the Amir. A successful Soviet campaign in August led to the establishment of the Bokharan Soviet Republic early in September. In the same month a treaty was signed with the Republic of Khwarezm, which had been established after the capture of Khiva, and a similar treaty was signed with Bokhara the following March. In April (1921) a decree of the All-Russian Central Executive Committee formally established Turkestan as an autonomous Republic. In March 1922 Enver Pasha began a campaign against the Soviet forces in Bokhara, and he was only finally defeated on June 26 at Bairin; Enver was assassinated in the following August in Bokhara.

Thenceforward all organised opposition to the Soviet administration ceased, though the Basmachi, adherents of the ex-Amir, continued to wage a guerrilla warfare against the Soviet authorities down to 1925. In Oct. 1923 Khwarezm was converted into a Socialist Soviet Republic by a congress sitting at Kiev, and in Oct. 1924 the Republics of Turkmenistan and Uzbekistan were formally admitted to the Union of Socialist Soviet Republics.

**Natural Resources.**—The climate of Turkomanistan and Western Uzbekistan is very dry; rain only falls in the spring and cultivation has to be carried on almost entirely by artificial irrigation. The average summer temperature is 30° C., and for the year 17° C. The population is largely nomadic, though wheat, rice, cotton and fruit are grown. Cotton planting has lately been intensively developed and large sums spent on irrigation; the area under cotton in 1926 has been estimated at 196,000 acres. Crops of all sorts are, however, uncertain owing to irregular water supply and to the ravages of locusts. Farther east the climate improves as country becomes more mountainous, and the Uzbeks (nomads of Mongol descent) breed horses, sheep, horned cattle and camels, and cultivate the river valleys. Artificial irrigation is being developed; the area so watered in the Oxus basin is to be increased from 405,000 ac. to over 3,000,000 by 1930 at a cost of £15,000,000. The area under cotton in 1926 had been increased to 1,515,000 acres. Fruit is also grown for export. The mineral deposits are as yet undeveloped, but uranium ore is sent to Kazan for the extraction of radium; coal, mercury, Glauber's

<sup>1</sup> The relative commercial efficiency of internal combustion and steam engines for high-speed passenger vessels. (*Trans. Inst. Naval Arch.*, vol. 67, 1925).

salt, rock salt and naphtha have been located. Silk weaving is still an important village industry.

**Communications.**—Considerable developments in the communications of Central Asia have taken place. The northern branch of the Central Asian railway has been extended from Tashkent to Pishpek and a further extension to Alma-Ata (formerly Vyerni) has been begun. The southern branch has been extended along the Oxus to Termez and a further extension to Dyushambe is in hand. The whole permanent way has been overhauled, and regular express services with dining and sleeping cars run to Tashkent. Road construction is also being taken in hand, and from March to Oct. regular air services link up Khiva, Termez, Dyushambe, Pishpek, Kagan and intermediate towns.

**BIBLIOGRAPHY.**—A. J. Toynbee, *Survey of International Affairs 1920-3*, pp. 428-445 (1925), and *id.* 1924, pp. 217-228 (1926). These works give some further references to the little literature available on this subject.

**TURKEY** (see 27.426).—The Republic of Turkey is bounded in Europe by Greece and Bulgaria, and in Asia by Syria, Iraq, Persia and the Union of Socialist Soviet Republics. The member of the Union which adjoins Turkey is the Transcaucasian Federal Republic, or more accurately two of its constituent States, namely the Republics of Erivan and Georgia. Inside the Republic of Georgia the port of Batum, together with that small part of the

lost her provinces in the Balkan Peninsula west of the River Maritsa, in which the Turkish element was in a minority. The core of the Empire, including the former capital, Constantinople, as well as Eastern Thrace and Anatolia, is intact. The area of the Republic is estimated at 494,450 sq. miles.

**Population.**—Under this head it is practically impossible to give even approximate statistics, owing to the succession of wars and forced migrations since 1911. Pending a census, the population of Turkey within her present frontiers at the present time may be conjectured to be between six and eight millions, though Turkish authorities give a much higher estimate.

As regards towns, Constantinople, while ceasing to be the political capital, has somewhat increased in population. Smyrna has decreased, owing to the exodus of the Greek and Armenian minorities, but has retained her commercial position, which depends on her geographical situation. Next to these two cities, Samsun and Adana would appear to have the greatest future. Angora, the present political capital, is a small town, and is unlikely to increase in population very rapidly, as it has no commercial or other economic advantages.

As contrasted with the former Ottoman Empire, the present

Turkish territory ceded to Russia in 1878 which has not been restored to Turkey by the Russo-Turkish Treaty signed at Moscow on March 16 1921, constitutes the autonomous republic of Ajaria, the population of which consists for the most part of Moslem Georgians.

The frontier which was last settled was that between Turkey and Iraq. Here the Council of the League of Nations had decided upon a certain line, but it was not until June 1926 that Great Britain and Turkey came to an agreement about it (see MOSUL). The present boundaries of Turkey practically coincide with those claimed in the Turkish National Pact of Jan. 28 1920 (see below), except that no plebiscite has been taken in Western Thrace, that the Batum district remains outside Turkey, and that most of the Mosul vilayet has now been assigned to Iraq. Whereas the former Ottoman Empire contained a number of autonomous territories, there is no territory within the present limits of Turkey which is not under the direct political control of the Government at Angora. The contingent autonomy provided for Northern Kurdistan under the Treaty of Sèvres was not reproduced in the Treaty of Lausanne (Aug. 6 1924). Comparing the territorial extent of Turkey in 1926 with that of the Ottoman Empire in 1911, it will be seen that the losses have been substantial in two quarters. Turkey has lost her Arab provinces in Asia and Africa, together with her suzerainty over Egypt, and she has also

Turkish Republic displays a relative homogeneity of population, owing to the exodus of Greeks and Armenians from Anatolia and Eastern Thrace and the immigration of Moslem elements from the lost territories in Europe, particularly from those which have passed under Greek sovereignty. The change is most marked in the Smyrna district and in Eastern Thrace, in both of which the Turkish element is now greatly preponderant. The only area in which the population still displays that extreme variety which was characteristic of the former Ottoman Empire is the urban district of Constantinople, from which non-Turkish Ottoman citizens legally domiciled there since Oct. 30 1918 have not been compelled to migrate. Apart from these non-Turkish elements in Constantinople and the Lazs (Moslem Georgians) in the northeast corner of Turkey in Asia, the present population of Turkey consists entirely of Turks and Kurds (see KURDISTAN). It is also to be noted that with the minorities there has disappeared that non-territorial system of communal autonomy known as the Millet system.

#### I. HISTORY AND EXTERNAL RELATIONS

In reviewing the history of Turkey since 1910 it is important to bear in mind that from the Italian declaration of war in Sept. 1911, to the signature of the Mudaniya Armistice in Nov. 1922, Turkey was almost continuously at war. The military events of this series of wars are recorded in separate articles (see ITALY-

TURKISH WAR; BALKAN WARS; WORLD WAR) and the present article is confined to political and social history. In order, therefore, to see this in perspective, it must be remembered that during the period under review Turkey has hardly been at peace, and that she has lost half her territory, besides transforming her internal organisation from top to bottom. The main features of the period have been this continual state of war and the revolutionary process of westernisation which has accompanied it and has been closely related to it. The relation can be seen in such examples as the emancipation of women, a movement which was greatly accelerated by the necessity which arose during the World War, in Turkey as elsewhere, to extend the field of employment for women in order to release men for military service.

The Ottoman Empire as it existed in 1911 still reflected the Ottoman Empire as it had been at its zenith. There was still a Sultan at Constantinople, who was recognised as Caliph of Islam by a large part of the Sunni Moslem world (including Sunnis as far afield as Russian Central Asia and British India), and this Sultan-Caliph was still guardian both de facto and de jure of the Holy Cities in the Hejāz (*q.v.*). Thus, although he had been reduced to virtual political impotence by the revolution of 1908, he was still an imposing figure, and the territories over which the Ottoman Govt. directly ruled extended to the east coast of the Adriatic opposite the heel of Italy in Albania; to the head of the Persian Gulf at the mouth of the Shatt al 'Aarb; to the southwest corner of Arabia in the Yemen, adjoining the British Protectorate in the hinterland of Aden; and to the provinces of Tripoli and Benghazi in North Africa. The Sultan also retained over Egypt a suzerainty, which was valid in international law though vague in its scope and not very effective in its application.

*The Balkan Wars.*—The first blow which the Ottoman Empire suffered during this period was the declaration of war by Italy in Sept. 1911. The Italo-Turkish War resulted in the loss of the North African provinces and in an Italian occupation of the Dodekanese group of islands off the southwest coast of Anatolia. On the other hand, considering how remote these African provinces were from the centre of Turkish power, and also the fact that Italy commanded the sea, the Turks put up a surprisingly good resistance to the Italian invasion. They persuaded the native population of Tripoli and Benghazi to make common cause with them, and took full advantage of the difficulties of the *terrain* and the climate. The course of this war showed that under such conditions the military advantages might not be wholly on the side of the more highly organised army, and this discovery, which was made by Enver Bey in 1911 and 1912, was afterwards applied by Mustafa Kemal Bey in 1919–22, when he successfully defended the Turkish homelands in Anatolia against the invasion of a Greek Army organised and munitioned by the Western Powers.

The Balkan Wars resulted in the loss of almost all the islands still remaining under Turkish sovereignty in the Aegean Sea and of the whole of Turkey in Europe up to the Chatralja lines. But Constantinople was saved from falling into Bulgarian hands, and when the Balkan Allies fell out among themselves, Eastern Thrace, including Adrianople, was recovered. The European frontier obtained by Turkey in 1913 was retained at the end of the period under review.

*The Baghdad Railway.*—After these losses of territory in Africa and Europe during the years 1911–3, the centre of political contention shifted to Turkey in Asia. Here the situation had been dominated by the disagreement between Great Britain and Germany over the Baghdad Railway, and by the lesser disagreement between France and Germany over the respective railway spheres of the two Powers in Northern Syria. During the year 1914 both these controversies were settled. On Feb. 15 a secret Franco-German agreement was signed, under which France gave Germany a free hand to carry forward the Baghdad enterprise in return for German recognition of French railway rights in Syria and Northeastern Anatolia. In June 1914 a more important and very comprehensive Anglo-German draft convention was initiated in London by Sir Edward Grey and Prince Lichnowsky, as a culmination to a number of separate agreements, between

the private British and German enterprises concerned, regarding river traffic on the Tigris, port construction at Baghdad, the exploitation of oil in Mesopotamia and the extension of the British Aidin Railway in Western Anatolia. Under the main agreement between the governments, Great Britain withdrew her opposition to the Baghdad Railway project, while Germany renounced the extension of the line beyond Basra to the coast of the Persian Gulf unless and until she obtained the consent of the British Government.

*The World War.*—These agreements between the Powers relating to Turkey in Asia, which seemed at the time to lessen the danger of a new European war over the Middle East, were thrown into the melting-pot by the outbreak of the War of 1914 and Turkey's intervention in it in the autumn of that year (*see MESOPOTAMIA, OPERATIONS IN; PALESTINE, OPERATIONS IN; and DARDANELLES CAMPAIGN*). It remains here to consider the motives of her intervention and its political consequences.

The Turkish Govt. had invited the German General Liman von Sanders to reorganise the Turkish Army immediately after the Balkan Wars, and he was appointed Commander of the First Turkish Army Corps, with Enver Pasha as his Chief of Staff, in Dec. 1913. According to the memoirs published under the name of Kemal Pasha (who with Enver and Talaat formed the triumvirate which governed Turkey during the World War) the Turco-German Alliance, binding Turkey to intervene in any general war in which Germany might be involved, had already been concluded before the War broke out. Whether or not Turkey did find her hands tied in Aug. 1914, she had powerful motives for intervention which sufficiently account for the course which she actually took. Her strongest motive was the temptation to fish in troubled waters. She had recently suffered great territorial losses. Now that the whole world was in the melting-pot might she not recover something for herself, Egypt for example? A more rational motive was the feeling that Russia was Turkey's mortal enemy, and that therefore Turkey ought to do everything in her power to prevent Russia from emerging victorious over the Central Powers. Turkish public opinion was also irritated by the commandeering of two warships which were on the point of completion in British dockyards. Her intervention was clinched by the arrival of the "Goeben" and "Breslau" at the Dardanelles. Germany promptly sold these vessels to Turkey to replace those which Great Britain had commandeered. The officers and crews were transferred to the Turkish service, and they forced the issue by shelling Russian Black Sea ports on Oct. 28.

The World War produced two general effects, one of which was favourable to Turkey and the other unfavourable. The first was the Russian Revolution of 1917, as a result of which the Tsardom in alliance with the Western Powers was replaced by the Soviet Govt., which soon came into open hostility with Russia's former allies. Thus, the country which had formerly been Turkey's most dangerous enemy was transformed into an opponent of Turkey's other enemies and therefore into Turkey's potential ally. The unfavourable factor was the Arab national movement, which was supported politically and militarily by Great Britain, with the result that Turkey lost all her Arab provinces in Asia. Meanwhile the partition of Asiatic Turkey, partly in favour of independent or semi-independent Arab States, but chiefly in favour of the Allied Powers, had been provided for under the so-called Secret Treaties (*see EUROPE, History*, pt. iii.) between Great Britain, France, Russia and Italy. In consequence of the Russian Revolution of 1917, the Russian claim to Constantinople, the Straits and Northeastern Anatolia was renounced. On the other hand, Greece had become a member of the Entente before the War ended. She participated in the occupation of the Straits which was carried out under the Armistice of Mudros (Oct. 30 1918), and at the Paris Peace Conference M. Venizelos put forward claims to Eastern Thrace and to the vilayet of Smyrna.

At the Peace Conference of Paris the representatives of the Principal Allied and Associated Powers failed to deal with Turkey, partly because they were pre-occupied with questions

Map showing the several partitions of the Ottoman Empire from 1908 to 26.

concerning Germany and her European allies, and partly because they were by this time in acute disagreement over the Turkish settlement, and therefore shrank from raising such a contentious issue. Meanwhile, though they were in effective naval occupation of the Straits, and in effective military occupation of the Arab provinces up to and beyond the Armistice line of Oct. 30 1918, their control was precarious in the Turkish homelands of Anatolia and Eastern Thrace. Moreover, both the Allied soldiers serving in the East and the Allied taxpayers at home were pressing their Governments to reduce as rapidly and as drastically as possible their post-War military establishments in this remote part of the world.

*The Smyrna Episode.*—In view of all this the Supreme Council of the Allies sought to maintain their military control over Turkey, pending the eventual settlement, by inviting Greece to land a military force at Smyrna. The landing took place on May 15 1919, under the protection of English, French and American warships. The immediate motive for landing Greek troops at this point and at this date arose from the fact that Italy had temporarily withdrawn from the Peace Conference on account of the Adriatic controversy, and that Italian troops had then landed at Adalia (Antalya) on April 29. Both Adalia and Smyrna had been assigned to Italy in April 1917, under the secret agreement of St. Jean de Maurienne; and though this agreement was technically invalid, Italy had a certain moral claim to secure the bene-

fits of it, and seemed inclined to make this claim good by independent action. The Greek landing had the very opposite effect to that which the statesmen responsible for it had intended. It was accompanied by atrocities, and it aroused an intense wave of national feeling in the Turkish people. The Mudros Armistice had left the Turks exhausted after seven years of war, and disillusioned with their former leaders. The triumvirate, representing the Committee of Union and Progress, which had made the revolution of 1908 and had recovered Adrianople after the Balkan Wars, had been compelled to flee the country, and their countrymen had been prepared to lose all their remaining non-Turkish provinces and even to accept the protectorate or mandate of the United States or Great Britain.

The Greek landing produced a revulsion of feeling and a revival of energy and the opportunity was seized by a new leader, Mustafa Kemal Pasha (*q.v.*), who had recently been sent by the Constantinople Govt. with the approval of the Allied authorities to Eastern Anatolia as Inspector General of the Forces. Under Mustafa Kemal's leadership a Turkish National Congress met at Erzerum in July and at Sivas in Sept., and the resistance of the local Turkish population to the Greek advance took on a national character. In Oct. Damad Ferid Pasha's ministry, which was favourable to the Allies, was replaced by one sympathetic to the Nationalists. A general election was held, the country returned a new Chamber which was overwhelmingly

Nationalist, and on Jan. 28 1920, during the session of this Parliament in Constantinople, a number of Deputies signed the so-called National Pact, which immediately became the creed of the national movement.

*The National Pact.*—In this document the Nationalists accepted the loss of the Arab provinces south of the Armistice Line of Oct. 30 1918; agreed to the opening of the Straits to international commerce; and proposed to grant to non-Turkish minorities the same rights as were secured to minorities in Europe under the various post-War treaties. On the other hand, the Pact demanded, either explicitly or implicitly, that Turkey should retain all territories inhabited by non-Arab Ottoman Moslem majorities, which meant not only Anatolia but Eastern Thrace and the Mosul vilayet; that Constantinople should be given military security; that the Millet system and the Capitulations should be abolished; and that there should be a reasonable settlement of financial questions.

The Allies and the Constantinople Govt. first attempted to overcome this movement by force. On March 16 1920, the Allies occupied the city of Constantinople, arrested a number of prominent Turks and deported them to Malta. In April the Sultan dissolved Parliament, and caused the Nationalists to be denounced by the religious and secular authorities of his Government. The only result was that such military control as the Allies had hitherto exercised in the interior was forfeited, and that the fugitive deputies from Constantinople reassembled at Angora, constituted themselves a National Assembly, and promulgated a law of fundamental organisation, in which they declared themselves to be the sole representatives of the Turkish national will. This seems to have been followed by the first overtures between Nationalist Turkey and Soviet Russia.

*Treaty of Sèvres.*—Meanwhile the terms of a Turkish settlement had at last been worked out by the Allied Powers at the San Remo Conference (*q.v.*); in May the draft terms were presented to a delegation of the Constantinople Govt., whose observations upon them were ignored; and on Aug. 10 a Peace Treaty was signed at Sèvres as well as a tripartite agreement between Great Britain, France and Italy, which gave partial effect to the secret treaties by laying out a French and an Italian sphere of influence in parts of those Anatolian territories which under the Peace Treaty were to be left under Turkish sovereignty. Eastern Thrace, almost up to the Chatalja lines and including the Gallipoli Peninsula, was assigned to Greece outright, and Greece was also given the administration of a zone round Smyrna (somewhat smaller than the territory of which she was then in military occupation), subject to a plebiscite at the end of five years.

These diplomatic instruments were a dead letter from the beginning. The Sèvres Peace Treaty had been signed by the Constantinople Govt., but meanwhile the whole of Turkey beyond the limits of Greek and Allied occupation had passed into the Nationalists' hands. When the Nationalist forces had begun to press upon the French in Cilicia and the British at Izmid, in the Asiatic hinterland of Constantinople, the Allies had accepted a proposal by M. Veniselos for a Greek offensive. This offensive had been executed successfully in June and July with British naval support, but though it brought the whole of Eastern Thrace and large additional districts of Anatolia under Greek occupation, it did not break either the military or the political strength of the Turkish Nationalists. In the autumn of 1920 the Nationalists attacked the Armenian Republic of Erivan, and at the same time the Bolsheviks produced a revolution there which resulted in the substitution for the previous Menshevik Govt. of a local Bolshevik Govt., which brought Erivan into the Soviet Union. These events in the Caucasus, together with the expulsion of General Wrangel from the Crimea, enabled Soviet Russia and Nationalist Turkey to join hands effectively against their common enemies, the Entente Powers. By arrangement with the Bolsheviks, the Turks compelled Erivan to cede about half her territory, including the fortress of Kars, which the Tsardom had taken from Turkey in 1878. The Nationalists' position was further improved by the defeat of M. Veniselos in the

Greek elections of Nov., and by the plebiscite recalling King Constantine, who was not *persona grata* with the Allied Powers.

In the London Conference of Feb.–March 1921 (*q.v.*) the Nationalists successfully insisted on being represented in addition to the Constantinople Government. The Conference was abortive, but the Allied Powers recognised in principle that the Treaty of Sèvres would have to be revised, and the French and Italian delegations negotiated secret understandings with the Nationalist representatives. These understandings were repudiated by Angora as being not sufficiently favourable to Turkey. Nevertheless they marked a definite breach in the diplomatic unity of the Allies which was never completely healed, and the French Govt.'s change of front had important consequences. The French Govt. was influenced by several motives: the difficulty of persuading the French people to provide the men and money for the arduous campaign which the Turkish Nationalists had forced upon France in Cilicia; the increasing jealousy felt by France towards Great Britain, whose naval preponderance gave her the leading rôle in the joint occupation of the Straits and Constantinople; and the French hatred of King Constantine, whose return finally alienated French sympathies from Greece. France now looked upon Greece as a country governed by an ex-enemy monarch and a country which promised to be a useful satellite to the principal rival of France in the Levant. Meanwhile Yusuf Kemal Bey, the Foreign Minister of the Angora Govt., had gone to Moscow and had there negotiated two important treaties, one with Afghanistan on March 1, and the other with Soviet Russia on March 16 1921. The latter treaty was followed by a supplementary treaty with the three Caucasian Soviet Republics, signed at Kars on Oct. 13, and a treaty with the Ukraine, signed on Jan. 2 1922.

*The Greco-Turkish War.*—The failure of the London Conference had led to a renewal of fighting in Anatolia. This campaign proved to be the turning point of the war. At the battle of İnönü in April the Greeks met with their first serious check at the Nationalists' hands. At the battle of the Sakariya in Aug. and Sept. their supreme effort to capture Angora and break the Turkish Nationalist resistance failed when it seemed within an ace of success. The Allies had already washed their hands of the affair. On May 18 the Allied High Commissioners at Constantinople announced the neutrality of their governments, and designated four neutral zones, one on each shore of the Bosphorus and the Dardanelles, upon which the belligerents were not to trespass. On Aug. 10 the Supreme War Council of the Allies pronounced that Greece and the Turkish Nationalists were engaged in a private war, and proclaimed the neutrality of France, Great Britain, Italy and Japan in formal terms. At the same time, France once more took separate action. In the autumn of 1921 M. Franklin Bouillon went to Angora, nominally on private business, and there negotiated an agreement (signed on Oct. 20), between France and the Turkish Nationalist Govt., under which France recognised that Government, evacuated her remaining holdings in Cilicia, and retroceded to Turkey a strip of territory, including the easternmost section of the Baghdad Railway, along northern border of the French mandated territory of Syria. The publication of this agreement was followed by an acrimonious correspondence between the French and British governments, but the agreement stood.

On March 22 1922 the Foreign Ministers of Great Britain, France and Italy met in Paris with the hope of persuading the governments of Athens and Angora to accept an armistice pending an agreed revision of the Sèvres Treaty. These proposals broke down on account of the Angora Govt.'s insistence that the Greeks should evacuate Anatolia as a preliminary to negotiations, and as the summer advanced the Greeks showed symptoms of desperation. On July 27, after strengthening their forces opposite the Chatalja lines, the Greek Govt. demanded permission from the Allies to occupy Constantinople. The Allies refused, and Greece accepted their decision. On July 30, again, M. Sterghiadis, the Greek High Commissioner at Smyrna, proclaimed the autonomy of the Anatolian territory under Greek occupation, with the apparent intention of continuing the

Anatolian War in the guise of a local Greek national movement, in case the Greek Govt. were compelled by diplomatic pressure to renounce their Anatolian claims. The Turkish Nationalists, however, who had also been hard hit by the life and death struggle of the preceding year, were in little better condition than the Greeks for opening another campaign, and at the beginning of Aug. 1922 Fethi Bey, the Minister of the Interior in the Angora Govt., arrived in London with conciliatory proposals for the neutralisation of the Straits under the control of the League of Nations. Fethi Bey failed to obtain an audience with any member of the British Cabinet, and on Aug. 4 (the last day of the parliamentary session) Mr. Lloyd George made a speech in the House of Commons in which such high praise was bestowed upon the military prowess of the Greeks that the speech was subsequently quoted by the Greek High Command in an order of the day. After staying for about three weeks in London without result, Fethi Bey left for Rome. It is reported that, before doing so, he telegraphed to Angora the advice to attack.

The Turkish offensive was launched on Aug. 26. The Greek army suffered a debacle. The Turkish army entered Smyrna on Sept. 9, and this dramatic decision of the Greco-Turkish War was accompanied by the wholesale exodus of the Greek and Armenian minorities from the re-conquered territory and by the Great Fire of Smyrna, which began on Sept. 13—two tragedies which might have been avoided if Western diplomacy had shown greater vision during the previous four years.

The Turkish victory over the Greeks had an immediate effect upon the military position of the Allies. With the Greek debacle, the screen of Greek troops which the Greek offensive of 1920 had interposed between the Turkish Nationalist forces and the Allied detachments on the Asiatic shores of the Straits, disappeared, and the Allied Govts. were faced with the necessity of making up their minds immediately on two points, first, whether they should oppose by force of arms any violation by the Turks of those neutral zones which the high commissioners had proclaimed on May 18 1921, and secondly, whether they should resist or accept the Turkish peace-terms as embodied in the National Pact. On the former question the British Govt. took the initiative, and secured diplomatic assurances of solidarity from France; but on Sept. 16 the British Govt. communicated to the Press a manifesto announcing that the British Dominions, Yugoslavia and Rumania, had been asked by telegram to promise military support, if necessary, for maintaining the freedom of the Straits. This manifesto not only threatened the Turks with military action at the line of the Dardanelles, but contained no reference to the Nationalists' territorial demands on the European side of the Dardanelles, in Eastern Thrace.

It thus offered the Nationalists an incentive for attacking the Allied detachments which were stationed at Chanaq, on the Asiatic side of the Narrows, before the reinforcements asked for could arrive. The consequence was that on Sept. 18 1922 the French Govt. ordered the withdrawal of the French troops from Chanaq within 24 hours. The Italian Govt. did the same, and thus, in face of the victorious Turkish Nationalists, the common diplomatic front of the Allies was utterly broken. Unity was restored by the exertions of Lord Curzon, who went to Paris on Sept. 19 and reached an agreement on Sept. 23 with M. Poincaré, under which both Powers accepted the British view regarding the temporary question of the neutral zones and the French view regarding the definitive peace terms. On the same day, in accordance with this agreement, the Principal Allied Powers invited the Angora Govt. to a Peace Conference on two bases: that Turkish sovereignty should be restored in Thrace up to the River Maritsa, and that during the interim period, pending the negotiation and entry into force of the Peace Treaty, the inviolability of the neutral zones should be maintained and the Turkish Army should be excluded from Thrace.

On the same date Turkish cavalry entered the neutral zone on the Anatolian side of the Dardanelles, and advanced almost up to the British wire at Chanaq. British troops in isolation were thus brought into direct contact with Turkish troops, and during

the next few days the situation was so dangerous that hostilities would almost certainly have broken out but for the tact and courage of General Harington, the British Commander-in-Chief of the Allied Forces in the Constantinople area, and his representatives on the spot. Meanwhile the Allied invitation of Sept. 23, which satisfied the Turkish demands on the vital point of the territorial settlement in Europe, eased the tension. On Sept. 29 the Angora Govt. accepted the invitation and suggested a preliminary armistice conference. This conference opened at Mudaniya on Oct. 3 and, in spite of a succession of crises, an armistice was signed on the 11th by representatives of Angora and the Principal Allies Powers, to which Greece acceded on the 14th. This opened the way to a Peace Conference, which began at Lausanne on Nov. 20 1922, and resulted eventually in the signature of a Peace Treaty at the same place on July 24 1923. The Treaty of Lausanne came into force on Aug. 6 1924 (see LAUSANNE, TREATY OF).

*The Nationalist Govt.*—The issue of the invitations to the Lausanne Conference on Oct. 27 1922 by the Principal Allied Powers was the immediate occasion for the liquidation of the Ottoman Govt. of Constantinople. An invitation had been sent to the Sublime Porte as well as to Angora, but Rafet Pasha, who had arrived in Constantinople on the 19th as Governor of Eastern Thrace on behalf of the Angora Govt., compelled the Porte to withdraw its acceptance of the invitation. On Oct. 30 the National Assembly passed resolutions against the Sultan-Caliph. On Nov. 1 it declared itself sovereign of Turkey, abolished the sultanate and the Ottoman Empire, voided all official acts of the Sublime Porte since March 16 1920, and assumed the right to elect future caliphs itself from among the members of the house of Osman. On Nov. 4 Rafet Pasha carried out a coup d'état at Constantinople; the Sultan's Govt. resigned; and therewith there disappeared a dynasty and an empire which had existed since the close of the 13th Christian century and had ruled from Constantinople since A.D. 1453. For the first time in its history Constantinople found itself not the capital city of the State to which it belonged. Constantinople was evacuated by the Allied forces and occupied by the Turkish Nationalist forces in Oct. 1923, after the coming into force of the Lausanne Treaty.

Like most revolutionary governments that have passed through trial to triumph, the Turkish Nationalists were bitter, not only against those of their countrymen who had taken the opposite side, but even against those who had been neutral or lukewarm during the critical years when the existence of the Turkish nation had been at stake. The first to suffer was the ex-Sultan-Caliph, Mehmed Vahyded-Din Efendi. On Nov. 17 he secretly made his way on board H.M.S. "Malaya," which conveyed him to Malta, and the Caliphate (shorn of all but its "spiritual" functions) was offered to and accepted by 'Abdul-Mejid Efendi, the cousin of Mehmed Efendi and the second son of the late Sultan 'Abdul-Aziz, who throughout the crisis had openly displayed his sympathy with the Nationalist cause. In addition to the ex-Sultan several other prominent opponents of the Nationalists, such as Damad Ferid Pasha and Riza Tewfik Bey, the philosopher, fled the country either before or at the time of the Nationalist victory. Others, including the surviving leaders of the Committee of Union and Progress, remained in discreet retirement.

A year later, the "counter-revolutionary" military courts, which the Turkish Nationalists had copied from the Bolsheviks during the time of crisis, were called back into activity by an incident of which the innocent causes were the Aga Khan and the Ameer Ali, the two distinguished leaders of the moderate element among the Moslem community in India. These gentlemen, who, from the Armistice onwards, had persevered in the rather ungrateful task of championing the Turkish Nationalist cause in Great Britain, and who had publicly based their claim to a voice on this subject upon the attachment of the Indian Moslem community to the Ottoman Caliphate, became alarmed during 1923 at the growing rumours of an intention, on the Angora Govt.'s part, to sweep away the Caliphate altogether, even in its attenuated form. They had

therefore addressed to the Angora Govt. a courteous letter explaining the Indian Moslem point of view, but they had sent copies of this letter simultaneously to certain reputable opposition journals at Constantinople, and the text had been published in their columns before it reached the hands of the Angora Foreign Office. The result was that summary proceedings were taken against the offending editors and that there was an open breach between the Turkish Nationalists and the leaders of the Indian Moslems (see CALIPHATE).

*Relations with Russia.*—It remains to follow the relations between Angora and Moscow. The overwhelming victory of 1922, which had brought the principal Allied Powers, as well as the Greeks, to their knees, released the Turkish Nationalists from their dependence on Russian support, and during the Lausanne Conference there was a significant divergence in the policy of the two Powers regarding the question of the Straits. Turkey and Russia had only been brought together by the pressure of their common struggle for life and death against the Entente Powers. When once this pressure was relaxed, their underlying difference of interest, which was founded on permanent facts of geography, began to reassert itself. Moreover, the doctrines of Communism and the new proletarian culture which the Bolsheviks were attempting to build up in Russia on that doctrinal basis had no attraction for the Turks, for Turks of all parties were under the glamour of Western civilisation in its French form, and the general aim of the Nationalists was to transform Turkey into a secularised bourgeois republic in the image of France herself. Thus, from 1923 onwards, there was a tendency for the friendship between Turkey and Soviet Russia to cool off, but this was counteracted to some extent by the continuance of controversies between Turkey and the Western Powers, and particularly by the Anglo-Turkish controversy over Mosul. The Soviet Govt. did not neglect the opportunity given to it by the decision adverse to Turkey which was rendered on the Mosul question by the Council of the League of Nations on Dec. 16 1925. On Dec. 17 1925, a new treaty was concluded between Turkey and Soviet Russia, in which either party promised the other its friendly neutrality in the event of diplomatic or military complications with a third party.

## II. CONSTITUTION AND ADMINISTRATION

Under the Constitution of April 20 1924, the Turkish State is a Republic, the State religion is Islam, the official language is Turkish, the seat of government is Angora, sovereignty belongs without restriction to the nation, and the Great National Assembly is the sole lawful representative of the nation and exercises sovereignty in its name (Articles 1-4). No proposal to alter or amend Article 1, specifying that the form of government is a republic, is to be entertained (Article 102).

This constitution is as different from the autocracy of 'Abdul-Hamid, and even from the constitutional monarchy of 1908-20, as the international position of the Turkish Republic is from that of the former Ottoman Empire. The internal revolution, however, has been a by-product of the Nationalists' struggle for independence against Greece and the Principal Allied Powers. In the National Pact there was nothing incompatible with the Constitutions of 1876 and 1908. It was the hostility of Sultan Mehmed VI. towards the Nationalists and his complacency towards the Allies which led the Nationalists at Angora to carry out an internal revolution contemporaneously with their struggle against foreign enemies. In the organic law of April 23 1920, the Great National Assembly constituted a Provisional Govt. at Angora; and the liquidation of the Sublime Porte in Nov. 1922 described above, left the Angora Govt. without a rival in Turkey, in fact as well as in pretension. Nearly a year elapsed before the formal declaration of the Turkish Republic was made on Oct. 29 1923, when the office of President of the Republic was also created and was conferred upon Mustafa Kemal Pasha. Down to this point the Government still retained a theocratic element, since the Caliphate had not been abolished, though the appointment had been placed within the patronage of the National Assembly and the office had been shorn of its politi-

cal powers. The expulsion of the Caliph 'Abdul-Mejid Efendi on March 3 1924 was accompanied not only by the total abolition of the office which he had held for 15 months, but by a drastic secularisation of the Turkish State in every department. The religious courts administering the Sheri'ah, or Islamic canon law, were placed under the National Ministry of Justice; Islamic educational institutions, from the mosque schools upwards, were placed under the National Ministry of Education; the Ministry of Evkaf, or Religious Endowments, was suppressed, the immense properties which it had administered being taken over by other departments of State; and the Sheikh u'l Islam, or principal jurisconsult in Islamic law, ceased to be an *ex officio* member of the Cabinet. These general measures of secularisation have been followed by divorce reform (which in Islamic countries means making divorce more difficult and not more easy), and by a law making the wearing of brimmed hats compulsory for Turkish citizens. This question is not so trivial as it might appear, and is intimately connected with religion. Hitherto, in Islamic countries, the wearing of a headdress with a brim has been the mark of an infidel, because it makes it impossible to touch the ground with the forehead in the exercises of prayer, according to the traditional Islamic ritual.

Apart from the secularisation of the State, the most interesting feature in the present constitution of Turkey is the concentration of power in the hands of Parliament.

*The Assembly.*—Indeed, the Constitution of 1924 explicitly confers upon the Turkish parliament powers even more extensive than the British parliament possesses by constitutional custom. The Assembly exercises the legislative power directly (Article 6), and the executive power through the intermediary of the President of the Republic, whom it elects, and through a Cabinet chosen by him (Article 7). Even the judicial power is exercised in the name of the Assembly, though the tribunals are declared to be independent (Article 8). The Assembly itself executes the Islamic law; makes, amends, interprets and abrogates secular laws; concludes conventions and treaties of peace with other States; declares war; examines and ratifies laws drafted by the Commission on the Budget; coins money; accepts or rejects all contracts or concessions involving financial responsibility; decrees partial or general amnesty; mitigates sentences and grants pardons; expedites judicial investigations and penalties; and executes definitive sentences of capital punishment handed down by the courts.

The Assembly is elected by manhood suffrage, every citizen over 18 being entitled to vote and every citizen over 30 being eligible for election (Articles 10 and 11). There has to be a general election at least once in every four years (Article 13) and a session at least once a year, lasting not less than six months, and beginning automatically on Nov. 1 (Article 14). Not only the President of the Republic or the Prime Minister, but a quorum of one-fifth of the deputies, may call a special session during recess (Article 19). The Chamber may hold secret sessions at its discretion (Article 20). The deputies enjoy the usual parliamentary immunities. No person may be a deputy and the holder of a public office simultaneously.

The executive power of the President of the Republic, as defined in the final text of the Constitution of 1924, is considerably less than it was in the first draft; but of course the actual power of President Mustafa Kemal was something very much greater than his constitutional position. This is due partly to his personal character and career, but also to the political inexperience of the Turkish nation, which can only gradually learn to avail itself fully of those wide powers of parliamentary self-government with which it is endowed by law.

*The President.*—According to the Constitution, the President of the Republic is elected by the Assembly from among its members for a period equivalent to that of the parliamentary term, the holder being eligible for re-election (Article 31). During his term of office the President may not take part in the discussions of the Assembly and may not vote (Article 32). He has a 10 days' suspensive veto, but the Assembly may re-pass a law over his head by a bare majority vote, and the veto does not apply at all either to constitutional amendments or to budgetary legislation (Article 35). The President represents the National Assembly as Supreme Commander over the army (Article 40). He designates the prime minister from among the deputies, and the prime minister chooses his colleagues, also from among the deputies (Article 44). The members of the cabinet, collectively and individually, and not the president, are responsible for the Government's policy (Articles 46 and 47). There is also to be a council of state chosen by the National Assembly (Article 51).

*Social Organisation.*—In another section of the Constitution (Articles 53-67), a judicial organisation is laid down on the most approved Western pattern, but this is still a programme rather than a reality. Another group of articles constitutes a kind of Bill of Rights, many of the clauses being practically identical with those

contained in the Minority clauses of the Lausanne Treaty (Articles 37-45 of the Treaty).

In general it may be said that if the full terms of the Constitution are eventually put into effect, Turkey will have become a thoroughly Western state; but at present this consummation is kept at a distance by the old obstacles to Turkish reform, namely, poverty and ignorance. Although primary education has been made universally obligatory and gratuitous (Article 87 of the Constitution), the percentage of illiteracy is still so great as to make effective popular self-government a distinct ideal, and even higher education in Turkey, though it is relatively more advanced, does not turn out trained and educated individuals in sufficient numbers to provide adequate candidates for any but the highest public positions. The poverty of the country, again, precludes the payment of adequate official salaries, and this not only makes the public service unremunerative and therefore unattractive compared with those business careers to which the new generation of Turks is wisely turning its attention, but it also places at least the minor officials under a constant temptation to supplement their emoluments by illegitimate means.

**Administrative Divisions.**—The old Ottoman Empire was divided into vilayets, or governor-generalships, which were satrapies of the dimensions of independent countries. These unwieldy areas have now been abolished, and the name vilayet has been transferred to provinces or departments of a manageable size. This change was foreshadowed from 1908 onwards by the separation of certain sanjaks from the old vilayets and their erection into independent units in direct touch with the central government. This reform has now been made systematic and universal, and at the same time the name "sanjak" has dropped out. The new vilayets, while they correspond to the old sanjaks in size, resemble the old vilayets and the old independent sanjaks in being in direct touch with the central government, and in being incorporated as juridical persons (Constitution, Articles 89-91).

**Education.**—The changes in Turkish education since 1911 have mostly been negative hitherto. Before that date education in the Ottoman Empire was largely provided for by the Islamic schools of all grades, from the mosque schools in the villages up to the theological seminaries; by the private educational institutions of the non-Moslem minorities; and by foreign educational institutions which were mostly of secondary, and in a few cases of university, grade. All these institutions have suffered from the wars and revolutions of the intervening period. The Islamic schools have been brought under the control of the secular Ministry of Education, the minority schools have practically disappeared with the minorities themselves, and the foreign schools have not only been brought under closer government control, but have lost a large part of their clientèle, which was formerly provided for the most part by the non-Moslem minorities. The Turkish Nationalists do not question the high standard maintained by these foreign institutions, nor the value of the standard as an example, but they point out with some justice that they had been founded originally with certain religious or political objects which may not be compatible with the free development of Turkish nationality. The foreign schools have been placed on precisely the same legal footing as private Turkish schools. They are now subject to government inspection; the teaching of Turkish language, literature, history and geography, by Turkish teachers approved by the Ministry of Education, has been made compulsory for a stated number of hours per week, and the compulsory attendance of Moslem pupils at Christian religious exercises has been forbidden. The Catholic schools were closed for some months owing to their refusal to remove the crucifixes from their class-rooms, and there were difficulties between the American College for Women at Constantinople and the Ministry of Education over the relation of the new medical department of the college to the Medical Faculty in Constantinople University. On the whole, however, the foreign schools have now successfully surmounted the difficulties which they encountered during the first years after the Mudania Armistice, and it is encouraging to note that the falling off in the number of non-Turkish pupils is rapidly being made good by the increased attendance of Turks.

In Turkish national education the chief need is the introduction of an efficient primary system throughout the country; but although this is provided for in Article 87 of the Constitution of 1924, lack of funds and lack of trained teachers are bound to make progress very slow. On the other hand, the University of Constantinople, which was nominally founded in 1900, but not effectively organised until 1918, is showing great activity in the face of financial difficulties. The old established faculties of law and medicine have been reinforced by faculties of arts and science, and co-education has become firmly established owing to the not unnatural unwillingness of the professors to deliver their lectures twice over to the men and women students separately.

### III. DEFENCE

**Army.**—Art. 40 of the constitution of Turkey states that, "The supreme command of the army is vested in the moral personality of the Great National Assembly and is exercised by the President of the Republic. In time of peace the command of the military forces is entrusted to the chief of the general staff within the limits of the corresponding laws. In time of mobilisation the command of the armed forces is entrusted to a person nominated by the President at the proposition of the Council of Commissars."

The land forces of the Turkish Republic in time of peace amount to: 163 infantry battalions, 42 field, 44 mountain, 5 howitzer and 27 heavy artillery batteries; 48 cavalry squadrons, 13 machine-gun mounted companies; 29 pioneer companies, 8 transport companies, 3 radiotelegraphic companies, 1 light-projector company and 8 field hospitals.

These forces are formed in 18 infantry and 5 cavalry divisions composing the IX. army corps, distributed over 3 military inspection regions. Each of these comprises 2 to 4 army corps, and is under a chief who is the designated commander of the corresponding army on mobilisation.

An army corps is normally composed of 2 infantry divisions, 1 heavy artillery regiment of 2 to 4 batteries, 1 squadron of corps cavalry, 1 technical company, 1 transport company, 1 automobile company and 1 company for communications and liaison. The VIII. army corps has no heavy artillery.

An infantry division has 3 infantry regiments of 3 battalions and 3 machine-gun companies each, 1 artillery regiment of 2 field and 2 mountain batteries, 1 pioneer company and 1 company for communications and liaison. The first 9 divisions are numbered from 1 to 9, while the remaining 9 divisions bear different numbers, inherited from the old organisation.

A cavalry division is composed of 3 cavalry regiments of 3 squadrons, 1 machine-gun mounted company and 1 to 2 mountain batteries each. The numeration of the cavalry divisions is also inherited from the old organisation.

The distribution of these forces is as follows:—

| Military Inspection Region | Army Corps and Headquarters                                    |
|----------------------------|----------------------------------------------------------------|
| 1st Angora                 | II. Balikesir<br>III. Constantinople<br>IV. Eskishehr          |
| 2nd Konia                  | I. Afun Qarahisar<br>V. Konia                                  |
| 3rd Diarbekr               | VI. Toqat<br>VII. Diarbekr<br>VIII. Erzinjan<br>IX. Sariqamish |
| 1st Cavalry Division       | Jeziret Ibn 'Omar (North of Mosul)                             |
| 2nd Cavalry Division       | Kirk-Kilisse (Thrace)                                          |
| 7th Cavalry Division       | Qara Kilissa (Anatolia)                                        |
| 8th Cavalry Division       | Van                                                            |
| 14th Cavalry Division      | Urfa (Turkish Mesopotamia)                                     |

In addition, the following other forces exist within the framework of the Army Corps:—

1. The National Guard of the Great National Assembly, consisting of 1 infantry battalion, 1 machine-gun company and 1 cavalry squadron.
2. 4 frontier commissariats of 4 battalions and 4 machine-gun companies each, in Artvin, Diarbekr, Adana and Adrianople.
3. 40 heavy batteries and technical units for the fortified places, namely: Smyrna, 8 batteries, 1 projector company and 1 pioneer company; Kara, 12 batteries, 1 pioneer company and 1 liaison company; Erzerum, 20 batteries and 1 liaison company; Chatalja, 8 batteries.
4. 16 batteries of coast artillery, at Samsun and other sea coast points.
5. 1 railway battalion, 1 pioneer and 1 liaison company.

Service in the army is obligatory. Its duration is 1½ years in the infantry and transport, 4 years for the navy and 2 years for all other arms.

The Gendarmerie represents a force of about 25-30,000 men, organised in 9 flying gendarmerie battalions and numerous companies, platoons and posts. There are also 5 mounted gendarmerie regiments, one each at Angora, Chorum, Yozghad, El 'Aziz and Erzinjan respectively. The recruiting is on a voluntary basis.

The equipment of the army is satisfactory, but it is not uniform. The rifles are of diverse types. The number of automatic rifles is only 1,200 to 1,300. The machine-guns are altogether about 800, *i.e.*, 40 for each division. The field guns are estimated to be about 600 to 650, but the reserve of shells is low. The cartridge factory in Angora is being steadily developed, but the production is insufficient.

*Air Service.*—The air service numbers 13 incomplete squadrons of 8 aeroplanes each, 2 schools for aviation (land and naval) in Smyrna. The instructors are French officers. The air units are concentrated in Smyrna, where there are 7 hangars for aeroplanes; others are being planned for construction at Afium Qarahisar, Mersina, Constantinople and Erzerum. A workshop for repairs exists also in Smyrna. The organisation of the meteorological service is not completed as yet and is to include 24 meteorological stations. The service will have the assistance of the existing radiotelegraphic stations and those under construction in Constantinople, Smyrna, Qastamuni, Gallipoli, Sivas, Angora, Eskishehr and Konia. Much attention is being given to the development of the air forces by the authorities and the public alike, who are raising donations and subscriptions for this end. The air services for postal and passenger service are only in embryo; it is served by aeroplanes of the German Junkers make.

*Navy.*—The naval forces are in an unsatisfactory condition. By the end of the World War the fleet numbered about 20 units, thanks to the German battle cruiser "Goeben" (which passed to Turkey in 1914) and some torpedo boats. By the Sèvres Treaty, only about 10 unimportant units were left to Turkey. By the Lausanne Treaty, however, Turkey got back the remnants of her fleet and moreover the liberty for further armaments. Turkey intends to entrust to a Japanese mission the development of her fleet, within the limits and necessities of a mobile defence to supplement the coast defence. To this end it is intended to repair and arm anew the cruisers Goeben, Hamidiye, seven gun-boats, two submarines and three torpedo boats. Further, within a period of 8 years, the construction is intended of 2 battleships, 2 cruisers of 10,000 tons each, 2 cruisers of 7,500 tons each, 4 destroyers, 12 torpedo boats (of 800 to 1,000 tons each), 4 submarines up to 1,200 tons each and 6 mine-layers. A sea dock is planned for construction at Izmid, where an inlet of the sea of Marmora has the shape of an easily defensible fjord. Two more naval aviation schools are planned (besides that in Smyrna); one in Constantinople and another in Trebizond, and 4 hydroplane stations. In the present situation the fleet can be used only for a defensive purpose, owing to its numerical and technical weakness and to the coastline of nearly 4,000 kilometres that has to be defended, especially the Aegean coast line where the opposite islands are in the hands of foreign states; but in the Black Sea it might to some extent take the offensive.

The mercantile fleet is developing rapidly in consequence of the provision in the Lausanne Treaty that the coastal and port services, as well as the fishing, are an exclusive privilege to the Turkish national flag, though exceptions have been made in the case of certain well-known lines. The steamship company "Seiri-Sefain" alone possesses a fleet of 60 units.

*The New Turkey.*—Sport and scout organisations are much in favour now all over Turkey, and are helped by the authorities. Other facts of a general character that are important from a military point of view are the reforms of Mustafa Kemal, which aim at the rousing of national pride and feeling by abolishing obsolete religious and political prejudices and introducing up-to-date methods. Moreover, the emigration and expulsion of the ethnical minorities have given a homogeneous basis to the State, and in this respect only the Kurds in the regions of the Mosul frontier remain as a source of disquiet for the Turks. The pervading conception seems to be that Asia Minor is the natural stronghold for Turkey, whose mission is rather in Asia in general, and that Thrace is only an advanced defence of the vulnerable points of approach of the Straits, in the same sense as Calais was one for England.

In the coming awakening of the Asiatic peoples, Asia Minor will probably have a paramount military importance at the meeting of the ways between East and West, and North and South, and as a reservoir of forces and a place d'armes for offensive action in any direction. The success in this rôle will be, of course, in correlation with the degree of modernisation of the railways and other means of communication, with the creation of industry and all other kinds of economic development on which military opera-

tions largely depend. All this is to a large extent lacking for the moment, although efforts are being made in that direction.

*Topography.*—From a topographical point of view, the salient feature of Asiatic Turkey is that it is a plateau, surrounded on three sides by the sea and by high ranges of mountains. This creates a double line of defence, one on the sea coast and another on the mountain ranges, especially on the northern and southern coast. The western coast, with its parallel valleys between the sea and the range of the inland plateau, is the more accessible one. On the east the plateau is guarded by the high Armenian mountains, extending far towards Persia and the Caucasus. In a general way and in the present situation as above described, Turkey is more advantageously situated for defensive rather than for offensive war.

#### POSSIBLE THEATRES OF WAR

1. *Northeastern Theatre.*—Against an enemy coming from the Caucasus and the Black Sea, the defence of Turkey is highly favoured by the mountainous character of the territory. There are four roads from Russia to Turkey. The one is along the coast, from Batum (terminus of the railway from Tiflis) to Trebizond. It passes between the coast and the mountain range of Lazistan and is not easy for movements. If the Turkish fleet is able to guard the coast, and on condition that some places are mined and Trebizond and Platana (Pulatkhan) are fortified according to their respective value, this route might be defended successfully with small forces. The second road is from Batum and Olti along the valley of the river Chorokh in the direction of Baiburt. The importance of this route consists in the possibility of turning the eventual positions along the line Kars-Erzurum-Erzinjan and of cutting the communication between Trebizond and Erzerum. The defects, however, are that not more than one or two army corps could move and act in this direction. The most important is the third route, the old classical road from Alexandretta on the Mediterranean to Tiflis and the basin of the Caspian Sea. At Erzerum it is crossed by the other classical road from Tehran to Trebizond. The railways Tiflis-Alexandropol-Kars-Erzurum, Tabriz-Nakhichevan-Alexandropol and the branch line Nakhichevan-Bayazid-Alashkerd are highly important in this respect and make possible military action on an extensive scale.

This zone contains some important centres, comparatively good roads and the possibility of movement of large forces on a wide front. The defence is favoured further by the fact that both Kars and Erzerum are successive fortresses, enabling the Command to pin the enemy until the decisive blow is delivered at his weak point. The railway in project, Angora-Qaisari-Sivas-Erzinjan-Erzurum, will be an important addition to the defence when constructed. The fourth route, giving access to Armenia and Kurdistan, runs from Erivan through Bayazid, and through the valley of the Murad-Tchai (upper course of the Euphrates) arrives at Melazkerd, from where there are roads for Erzerum, Bitlis, Diarbekr and Kharpüt. If the positions at Melasgerd and Rehova-Getchidi (North of Bitlis) are fortified, they might serve as a fortified camp for securing the flank. Once an enemy has succeeded in overcoming all the defences in the mountainous country of Armenia and Lazistan, and has reached the plateau of Asia Minor, he will have gained full liberty of movement towards Constantinople, encountering serious defence lines only at the rivers Yeshil Irmağ and Qizil Irmağ. Such an advance, however, will possibly imply the detaching of large forces towards Diarbekr, for guarding the approach from the direction of Mesopotamia, and towards Gazi-'Aintab, for guarding the approach from the direction of Syria.

Against an enemy from the Black Sea, Asia Minor has the advantage as already mentioned, of its double line of defence—the sea coast and the range of the plateau (the same being on the side of the Mediterranean), a first defence being offered on the sea coast and the decisive one on the range of the plateau. If the network of railway lines is completed, this will give the defence high possibilities for manoeuvre. Landings on a large scale could not be expected, therefore, on the Black Sea coast. Small landing operations, however, are possible in connection with an advance from east to west. Even these, owing to the lack of roads for the interior of the country, are possible only at Trebizond, Kiresün, Ordu, Samsun, Sinob, Ineboli, Amasra and Eregli. On the coast between Sinob and Constantinople there is only one high road for the interior of the country, *i.e.*, Ineboli-Qastamuni-Kanghri-Angora.

2. *Thracian Theatre.*—Owing to the demilitarised zones along the frontiers with Greece and Bulgaria and on the Straits (Bosporus and Dardanelles), the defence of Thrace is important in the sense of a tête-de-pont, serving for the defence of Asia Minor itself, along the important water line Bosporus-Marmora Sea-Dardanelles, on its European side. A defence far in the interior from the coast of the Sea of Marmora, *i.e.*, at Adrianople and Chori, in some respects might be useful for Turkey, but the Straits remaining unfortified, the flanks would be highly endangered. The real line of defence remains the line of the Bosporus and Dardanelles. In this respect the Asiatic coast of the Sea of Marmora has a very important bearing,

especially with its numerous fjord-like bays. It should be remembered, moreover, that the demilitarised zones in time of war might be quickly fortified by far-seeing and well-armed people. It should be admitted therefore that the Turks might be compelled to fortify the Bosphorus and the Dardanelles; these being, further, the points of contact between two great empires—Britain and Russia. Any one of them contemplating an attack on the Straits would probably compel the other to lend its help to Turkey. The defence might be greatly favoured if Turkey was in possession of a large air force and of powerful artillery, which would enable her to defend the Straits even with positions of a temporary fortification.

3. *Agean Theatre*.—This coast is more easily accessible for an enemy than the Black Sea or Mediterranean Coast, owing to the fine harbours and numerous parallel roads to the interior far up the plateau. The country, moreover, is the richest of all Asia Minor, it being the cradle of ancient civilisations. But, although the islands off the coast, the Dodecanese, are not in the hands of the Turks, with good manoeuvring they might make difficult any landing operation, since good roads and railways are available in these regions. With a reliable fleet of submarines and torpedo boats or mine-layers, and owing to the numerous harbours, they might endanger the sea communications of the landed force. Further, and after an enemy has succeeded in getting hold of all that vast territory, he would have to face the enemy in a decisive resistance at the range of the plateau, on the watersheds of the rivers Sagariya and Meander. Greek experience in 1922 showed the difficulties even for an invader whose enemy was badly armed.

4. *Mediterranean Front*.—This coast, from Maqri to Alexandretta, has the same features in general as the Black Sea coast, presenting a double defence line. In addition, the range of the plateau, *i.e.*, the Lycian and Cilician Taurus and the Anti-Taurus are higher and steeper, with no good roads for the interior. Suitable places for landing are Mermeris, Maqri, Andifilo, Antaliya (Adalia) 'Alaya, Selendi and Peyas. Only the four latter have behind them a sufficient hinterland for the development of serious military action. Not far from the coast is the road of old military conquerors, Konia-Adana-Aleppo, through the defile of the "Cilician Gates." Parallel to it is the railway Aleppo-Damascus and Aleppo-Baghdad. A landing at Mersin would have the advantage of enabling the organising of a large tactical landing base (*tête-de-pont*), with greater security and quickness. The region itself, with Adana as a centre, although exposed to malaria, is rich and would help the supply of foodstuffs. From that region five operative directions radiate towards Diarbekr, Kharput, Sivas, Angora and Eskishehr.

5. *Syrian Theatre*.—This is the converging point of roads and railways between Europe, Asia and Africa. For an enemy coming from Syria, with the desert on the East and the sea on the West guarding his flanks, it would be possible to create a secure place d'armes from which he might dominate the road to Africa, cut the road to Baghdad, or else undertake an advance towards Konia, Qaisari, Kharput and Diarbekr. Further, the bay and harbour of Alexandretta are very safe.

6. *Mesopotamian Theatre*.—It is divided by the railway Adana-Mosul into two halves. The northern one, in the possession of Turkey, is inhabitable and with sufficient roads. On the north it is dominated by the Armenian Taurus, standing between the Euphrates and Tigris like a snow-covered wall in face of the immense plains of Syria and Mesopotamia. The possession of this wall between Bitlis and Kharput ensures the sally-ports from the Anatolian plateau towards Aleppo and Mosul. The southern half of this theatre includes the territory south of the railway, which is part semi-desert, part of desert and mountainous character. The territory between Birejik-Meskene-mouth of the river Khabur to Jeziret Ibn 'Omar, is of semi-desert character, although yielding good produce. It is inhabited by nomad Arabs and Kurds. Military operations are very difficult, almost impossible. The same characterisation applies to the territory along the Tigris, from Jeziret Ibn 'Omar to Jebel-Hamrin, south of Mosul. In the remaining part, from the mouth of the river Khabur to Baghdad, the territory is desert, and only west of Mosul, on the mountain range of Sinjar, where the oil deposits are situated, nomads live in the summer, coming back in the plains in the winter. The importance of this theatre of war is that from here it is possible to cut the road from Kars to Angora, or else, on the contrary, to undertake an advance towards the Persian Gulf. The remains of old fortresses in Diarbekr, Mardin, etc., show that in old times here was a theatre of serious operations. In an advance from 'Iraq, the defence of Turkey would be favoured by the mountains of Hakiari, Tur-Abdin, Diarbekr and Qaraja Dag, being the forefront of the Armenian Taurus, where the decisive operations of a campaign could take place.

7. *Persian Theatre*.—In its northern part it has a first-class route for movement. This is the old road from the Iranian Plateau to the Black Sea, from Tehran, through Tabriz and Bayazid, to Trebizond. The other routes are of a secondary importance and do not lead to important centres; besides, they pass often through waste land. From Tehran to Van there are two roads, the one going through Tabriz-Dilman and the other through Urmia-Bash Qale. In a general way, this theatre has a relative importance if only for use in connection with operations from the Caucasus to Angora or from Armenia to 'Iraq.

(P. D.)

## IV. FINANCIAL AND ECONOMIC HISTORY

*Population*.—According to the official registers the population of Turkey in 1925 was 13,560,000, but as there has been no census in recent years, and as the registries of 135 kazas were destroyed by enemy action, the exact population is not definitely known. Considerable changes have taken place in the composition of the population in some districts, and since the exchange of population agreement between Turkey and Greece, 397,000 immigrants have moved into Turkey and have been settled in different localities. The Turkish Govt. has endeavoured to increase the health and strength of the population, and special measures have been taken by the Ministry of Public Health for the prevention of infant mortality, tuberculosis and malaria, which are having their effect on the population figures.

*Finance*.—In March 1912 an Act of Public Accountancy (*loi de comptabilité*) came into operation. This Act based the budget system and the accounting methods of the State upon sound financial principles adopted by most European States—in particular, the authorisation of expenditure by Parliament, the annual budget, proper auditing of the accounts and the centralisation of revenue in the Ottoman Bank. The financial reforms made by the Ottoman Government have been maintained by the Turkish Republic, and the Act of 1912 is still in force. During the first year of the Nationalist Govt. financial control was exercised by a group of deputies elected from the Great National Assembly, but in 1923 an Act was passed establishing an audit department (*Divan-i Muhasebat*), the members of which are specially nominated by the Assembly and responsible to it.

Public accounts for the period under review show the following results:—

| Year    | Ordinary expenditure authorised | Supplementary and extraordinary expenditure authorised | Revenue estimated in the budget |
|---------|---------------------------------|--------------------------------------------------------|---------------------------------|
|         | £T.                             | £T.                                                    | £T.                             |
| 1911-2  | 36,233,000                      | 3,044,000                                              | 28,445,000                      |
| 1912-3  | 33,997,000                      | 13,131,000                                             | 30,514,000                      |
| 1913-4  | 33,997,000                      | 14,136,000                                             | 30,514,000                      |
| 1914-5  | 34,012,000                      | 16,300,000                                             | 32,607,000                      |
| 1915-6  | 35,657,000                      | 18,032,000                                             | 26,836,000                      |
| 1916-7  | 39,724,000                      | 44,249,000                                             | 25,012,000                      |
| 1917-8  | 53,304,000                      | 47,435,000                                             | 23,584,000                      |
| 1918-9  | 51,969,000                      | 79,748,000                                             | 34,016,000                      |
| 1919-20 | 51,969,000                      | 40,761,000                                             | 34,016,000                      |

<sup>1</sup> It will be seen that the estimates show a constant and heavy deficit, which, however, must not be taken at its face value, as in practice considerable amounts of the money annually allotted to various services were not expended.

The Italian War in 1911 and the Balkan War in 1912 were disastrous for the financial situation of the Empire. The budget deficits were covered until the World War by loans obtained from France and elsewhere; but during the World War by loans and advances obtained from Austria and Germany and by certain War taxes.

In Sept. 1914 the capitulations were suppressed, which enabled customs duties to be increased and a tariff to be drawn up in conformity with the economic and financial needs of the country. When the Government of the Great National Assembly established at Angora (April 23 1920) took the financial administration of the territories under its rule, it was unable to draw up a regular budget as the nation was engaged in repelling invasion. Hence in the years 1920-4 the country was financed by advances which were under the direct supervision and control of the financial committee of the Assembly. The Treasury accounts, with the "*loi de règlement définitif*" for 1921 and 1922, were presented to the Assembly and published in 1925.

According to the reports of the audit department of the assembly, the allocations for the period March 1924-April 1925 were £T. 176,993,431, of which £T. 32,287,000 were not actually expended. The revenue received in that year was £T. 137,729,696. The estimated revenues for 1924-5 and 1925-6 are given in the table on the following page.

|                                              | 1924-5                  | 1925-6                  |
|----------------------------------------------|-------------------------|-------------------------|
|                                              | £T.                     | £T.                     |
| Direct contribution                          | 43,930,500 <sup>1</sup> | 39,870,500              |
| Stamps and registration duties               | 3,210,000               | 5,445,000               |
| Indirect contribution                        | 28,170,000              | 35,555,000              |
| Monopolies                                   | 16,044,100              | 27,800,000 <sup>2</sup> |
| Commercial and industrial state undertakings | 703,000                 | 1,720,000               |
| Domains                                      | 4,480,000               | 14,965,000              |
| Various receipts                             | 5,424,010               | 8,731,354               |
| Consumption tax                              | 14,461,000              | 16,360,000              |
| Extraordinary tax for war                    | 12,792,000              | 2,500,000               |
| Total <sup>3</sup>                           | 129,214,610             | 153,046,854             |

<sup>1</sup> £T. 27,500,000 of this item was obtained from tithes. To free the peasant from the payment of a tax on all crops which he consumes, or which he can dispose of in his district, an Act was passed in Feb. 1925 suppressing this tax and replacing it by a six- to eight-fold increase of the real property tax, to allow for depreciation of the currency; and by another tax equivalent to 8-10% of the value of the crop directed to port or station.

<sup>2</sup> Under an agreement between the Government and the tobacco régie the concession was to expire on March 1 1925. The Assembly promulgated a provisional law authorising the Government to administer the tobacco régie in its existing form for a period of one year, subsequently extended for three further years. A state monopoly for the sale of cigarette paper was established.

<sup>3</sup> In comparing these figures with those given before the depreciation of the currency must be taken into account (see under *Currency* below).

**Currency.**—No other paper money has been issued than that put in circulation by the Ottoman Empire during the World War. The amount issued then was £T. 160,018,665, of which £T. 17,270,101 has been withdrawn. At the beginning of 1926 the Turkish exchange on London was 912 piastres to the pound sterling, compared with a par value of 110 piastres. In 1924 and 1925 the highest rates were 888 and 965 piastres respectively and the lowest rates 790 and 805 respectively.

**Banking.**—In April 1925 the concession of the Ottoman Bank was extended, subject to a number of new conditions, until March 1935. The privilege of the bank to issue notes was confirmed, but is only to be exercised when the Turkish lira is re-established on a gold basis. The right of the State to establish a bank of issue is expressly maintained.

Banking is progressing in Turkey, and new banks have been founded with Turkish capital. The most important of these are Ish Bankassi, or Banque de Travail (capital £T. 1,000,000), Banque de Commerce et d'Industrie (capital £T. 1,000,000), Akhissar Tobacco Bank (capital £T. 500,000), Akshehir Bankassi (capital £T. 1,000,000), and a new Bank of Turkey for Mining and Industry established in April 1925. Ish Bankassi, since its establishment, has opened three branches in the chief cities of Turkey, and has given assistance in forming many industrial, financial and mining companies. It also co-operates with foreign capitalists in obtaining concessions for railway construction, timber, mining and industrial enterprises.

There is a serious credit stringency which hampers industry and commerce. While the total of exports and imports exceeds £T. 500,000,000 annually, the credits given by the banks to traders do not exceed £T. 40,000,000, and Turkish traders have to pay very high rates of interest. Branches of foreign banks operating in Turkey extend facilities to their own nationals trading there, but not as a rule to Turkish traders, even where the security is good; hence the need for a national credit institution is keenly felt.

**Communications.**—In 1914 the total length of the railway system of the Ottoman Empire was 6,733 kilometres. As a result of the World War and subsequent adjustments there was a net loss of 2,640 km. of railways. The greatest importance is attached by the Govt. of the Republic to railway development, and Ismet Pasha's Cabinet is doing all it can to further the construction of new railways, which are to be managed in future by the State. A number of railways are in process of construction and several are nearing completion, amongst which may be mentioned the Angora-Sivas line (620 km.); the Samsun-Sivas line (410 km.); the Angora-Eregli line (370 km.). In spite of comparatively

small experience, the Turks have shown skill and ability in railway management and construction. The total length of Turkish railways worked in 1925 was 14,407 kilometres.

**Agriculture.**—Turkey is essentially an agricultural country, but the development of the very considerable natural wealth of the land has been hindered in the past by inadequate transport, by the tithe on gross produce and by very backward methods of cultivation. The Govt. of the Republic is engaged in remedying the first defect by the construction of railways; the tithe has been transformed into a tax on farm produce after it has been brought to markets other than the one local to the place of growing, and at the same time the land tenure, inheritance and mortgage laws are being modernised; finally steps have been taken to improve seed selection and to introduce agricultural machinery.

Twelve agricultural schools were established in 1922 and 1923 in different cities, and model farms have been started at Siverek and Diarbekr to encourage the use of scientific methods by the peasants. In 1924 two sericultural institutions and a seed-selecting station were founded, and a European specialist was engaged for the latter. Financial assistance is given by the Ministry of Agriculture to those engaged in the industries of dairy farming, silkworm rearing and bee-keeping.

The use of machinery is increasing, and the farmers who employed primitive methods are now utilising modern machinery. There are in Turkey 3,700 ploughs, 70 threshing machines, 1,223 tractors, 96 motor ploughs and 1,505 sorters, and large numbers of machines have been imported for the improvement of seed. Nine repairing shops have been established, and mechanical departments have been attached to the agricultural schools of Angora and Adana.

In the past great damage was done to the crops by locusts, and no effective measures were taken till 1915, when a German expert was engaged and the locusts were practically exterminated. During the Greek occupation the locusts increased again and wrought much harm. In 1925 the same measures were put into operation, and it is probable that in a few years the districts infested will be freed from the pest.

The area under cereals in 1924 in 369 kazas is shown in the following table:—

| Kind of cereal | Hectares  | Proportion under each crop | Proportion to total area | Production in 1913 in bushels |
|----------------|-----------|----------------------------|--------------------------|-------------------------------|
| Wheat          | 1,683,501 | 50.30                      | 2.60                     | 152,000,000                   |
| Barley         | 956,670   | 28.58                      | 1.47                     | 93,400,000                    |
| Oats           | 77,731    | 2.32                       | 0.11                     | 12,700,000                    |
| Kablidja       | 78,407    | 2.34                       | 0.10                     | 6,714,000                     |
| Maize          | 296,613   | 8.06                       | 0.45                     | 21,460,000                    |
| Rice           | 17,971    | 0.54                       | 0.02                     | 1,892,000                     |
| Millet         | 79,259    | 2.37                       | 0.12                     | 4,715,000                     |
| Rye            | 114,428   | 3.42                       | 0.17                     | 11,971,000                    |
| Miscellaneous  | 69,206    | 2.08                       | 0.10                     | 1,463,000                     |
| Total          | 3,373,786 | 100.00                     | 5.16                     | 306,315,000                   |

The area under cereals in 1924 was 26% less than in 1913. The following estimate shows the value of the pre-War and 1923 production of the chief agricultural products exported by Turkey:—

|         | 1913 value of production<br>1,000 £ T. | 1923 value of production<br>1,000 £ T. |                     |
|---------|----------------------------------------|----------------------------------------|---------------------|
|         | (Gold)                                 | (Gold)                                 | (Paper)             |
| Opium   | 1,000                                  | 562                                    | 4,500               |
| Mohair  | 640                                    | 400                                    | 3,200               |
| Wool    | 640                                    | 150                                    | 1,200               |
| Cotton  | 840                                    | 625                                    | 5,000               |
| Nuts    | 1,760                                  | 1,025                                  | 8,200               |
| Tobacco | 3,200                                  | 2,220                                  | 17,600              |
| Silk    | 1,000                                  | 175                                    | 1,400               |
| Total   | 9,080                                  | 5,157                                  | 41,100 <sup>1</sup> |

<sup>1</sup> Here again the changed value of the lira must be taken into account.

**Minerals.**—The legal conditions under which minerals and oil can at present be prospected and extracted are now (1926) under consideration, and amendments are proposed which it is hoped will increase the interest of capitalists, and hasten the development of the country's resources. Mining experts have discovered that the land running parallel to the Black Sea from Eregli to Ineboli is rich in coal, and that quantities of copper, lead, chrome, emery, tin and manganese are to be found in different parts of the country. The concessions of the copper mines of Ergeni, the lead mines of Bulgardagh and the chrome mines of Kiutahia have been given to two companies with capitals of £T.3,000,000 and £T.1,000,000 respectively. The Turkish Govt. has supplied 51% of the capital of these companies, while 49% is provided by German capitalists represented by the Metallgesellschaft and the Deutsche Bank. In 1924 the chief mineral output of Turkey was: 14,805 tons of emery, 132 tons of antimony, 10,007 tons of bandermite, 3,700 tons of lead, 450 tons of copper, 2,500 tons of chrome ore, 769,100 tons of coal, 200 bottles of mercury and 988 cases of meerschaum.

**Industry.**—The Government of the Republic is doing its utmost to encourage the expansion of industry, and for this reason has exempted industrial factories built by Turkish subjects (the capital may be foreign) from income tax and real property tax. The importation of materials for use in the construction of factories, and of a number of other important raw materials not found in Turkey, has been exempted from customs duties. Special railway and other facilities have been given in the case of sugar to encourage the erection of sugar factories, and in general the policy of the Government is to favour the setting up of factories which draw their raw material (e.g., cotton, wool and sugar) from within the country. Since the establishment of the Republic 60 new factories of different kinds have been built. The following table shows the output of carpets in Smyrna and the surrounding district:—

|                                                          |                          |
|----------------------------------------------------------|--------------------------|
|                                                          | sq. arshins <sup>1</sup> |
| Before the World War . . . . .                           | 1,834,000                |
| During the Greek occupation 1919–Oct. 1923 . . . . .     | 1,368,000                |
| After the Greek evacuation Oct. 1923–Oct. 1924 . . . . . | 1,256,000                |
| Oct. 1924–Oct. 1925 . . . . .                            | 1,646,000                |

<sup>1</sup> An arshin is 26·96 inches.

**Shipping.**—By the Lausanne Treaty the right of cabotage (coastwise shipping) is confined to Turkish ships, and as a result of this provision Turkish ships have increased in numbers, but their progress is hindered by the shortage of credit. In 1925 the number of Turkish steamships was 170 of 95,286 tons and the number of sailing vessels 3,745 of 115,767 tons.

The following table sets out the port traffic in 1924 at the principal ports:—

| Port and dependencies    | Turkish ships |           | Foreign ships |           |
|--------------------------|---------------|-----------|---------------|-----------|
|                          | No.           | Tonnage   | No.           | Tonnage   |
| Constantinople . . . . . | 30,146        | 1,833,971 | 4,019         | 5,445,110 |
| Smyrna . . . . .         | 8,451         | 616,355   | 2,330         | 1,356,566 |
| Samsoun . . . . .        | 19,949        | 3,541,060 | 493           | 856,041   |
| Mersin . . . . .         | 5,802         | 257,439   | 2,112         | 736,550   |
|                          | 64,348        | 6,248,825 | 8,954         | 8,394,267 |

**Commerce.**—The principal exports from Turkey are tobacco, dried fruits and nuts, wool, mohair, opium and cotton, while the principal imports are manufactured products such as cotton goods, woollen goods, metals and machinery, leather and leather goods, etc. The following tables show the values of the chief imports and exports and their distribution:—

| Year | Raisins<br>Tons     | Figs<br>Yuk <sup>1</sup> | Tobacco<br>Kilo | Cotton<br>Bales | Acorns<br>Tons |
|------|---------------------|--------------------------|-----------------|-----------------|----------------|
| 1922 | 37,400 <sup>2</sup> | 128,000                  | 6,900,000       | 8,000           |                |
| 1923 | 40,300              | 130,000                  | 10,000,000      | 9,500           |                |
| 1924 | 51,800              | 135,000                  | 23,000,000      | 27,000          | 27,500         |

<sup>1</sup> One yuk is approximately 220 kilo. <sup>2</sup> Greek occupation.

### Import and Export by Commodities

**Public Debt.**—By Art. 47 of the Lausanne Treaty it was stipulated that the debt charges on the pre-War foreign debt should be allocated between Turkey and the territories detached from the Ottoman Empire, and that the allocation should be made within three months of the coming into force of the treaty. The council of the Ottoman debt accordingly allocated the annuities and notified the States concerned; certain States protested against the allocations, and the questions in dispute were referred to the League of Nations, which appointed Professor Eugène Borel as arbitrator. On April 18 1925 he gave his decision establishing the share of each State. Under this decision the shares are distributed in the following proportions: Turkey 62·25%; Greece 10·57%; Serbia 5·25% (but Serbia refuses to be responsible for any part of the Ottoman debt and has withheld her signature from the Treaty of Lausanne); Syria and Greater Lebanon 8·17%; Iraq 3·96%; Palestine 2·47%; Bulgaria 1·63%; Albania 1·57%; Italy 0·23%; other Arab States 3·90%.

Representatives of the French, British and Italian bondholders met the Turkish Delegation in Paris in July 1925, to arrive at a *modus operandi* regarding the payment of the Turkish quota, the nominal capital of which is £T.84,597,495, and to discuss any concessions that might be granted in view of Turkey's financial condition. But by the end of Feb. 1926 no satisfactory agreement seemed possible whilst the attitude of Turkey was maintained. An incomplete payment by Palestine was the only payment made since the ratification of the Treaty. None of the States had in 1926 furnished the guarantees required by the treaty. The French Govt. had proposed to offer the customs receipts on behalf of Syria and the Lebanon, and the Greek Govt. offered the surplus of the revenues assigned in Greece. The Turkish Government continued to appropriate the revenues assigned under the decree of Mouharrem and the other loan contracts.<sup>1</sup>

<sup>1</sup> At the end of May 1926 it was announced that the negotiations which had been going on for nine months between the Turkish Government and the bondholders in Paris for a settlement of the Turkish Unified Debt had broken down. Under the decree of Mouharrem (of 1881), any interpretation of the terms of the contract with the bondholders was to be referred to arbitration. By the Treaty of Lausanne the Turkish share of the debt was reduced to £T.84,597,495, but no payments have been made, the Turkish Government having appropriated the assigned revenues to public purposes pending the settlement of the dispute. (Ed. E.B.)

**TURKMENISTAN**, a Soviet republic in Central Asia. (See SIBERIA; TURKESTAN.)

**TURNOVER TAX.**—A turnover tax, in its fullest sense, may be defined as a general excise tax charged cumulatively, though at a low rate, upon successive turnovers of goods (whether raw materials, goods in course of manufacture or finished articles) and services, or, expressed in different words, upon the gross receipts of producers, distributors, professional and commercial business men, etc. Like other excise duties, the tax is an indirect tax intended to fall ultimately upon the consumers of the goods, etc., in respect of which the duty has been levied. General sales taxes always spring from urgent financial necessity, and accordingly the demoralised condition of national finance, following the World War, led to a considerable crop of turnover or sales taxes. For example these were imposed in France, Belgium, Italy, Germany, Czechoslovakia, Hungary, Rumania and the Serb-Croat-Slovene State.

The scope of the various turnover taxes in force varies very greatly. Some extend to all transactions in goods, whether wholesale or retail. Others are limited to wholesale transactions in goods only. Usually there is a flat rate for all transactions, though differential rates for specified transactions are sometimes found. The opportunity is occasionally taken to combine luxury taxes with a turnover tax. Exemptions are granted of various kinds and weights, while services may be taxed here and exempted there or divided into categories receiving special privileges elsewhere. The treatment of imports and exports varies; public utility undertakings are exempted in one country and are liable in another. This extraordinary complexity makes it impossible to describe the actual taxes in force and, accordingly, in the paragraphs which follow, consideration is limited to the main principles of the tax.

#### CHARACTERISTICS OF THE TAX

Just as an income tax applies in theory to all income, so a turnover tax is applicable in theory to all sales of goods and services. Accordingly, subject to exemptions and variations, the tax attaches to almost every transaction of life and to every ingredient in those transactions.

Its second feature is its cumulative operation. Raw materials, out of which the finished goods are fashioned, pass through many processes of manufacture, treatment and distribution. Normally, these various processes are carried out by different classes of business, owned by different concerns. A turnover tax is payable on every transfer of the goods from the first sale of raw material down to the final sale to the ultimate consumer of the finished article. Value is added to the product at every stage and, accordingly, the amount of the tax grows larger at each transfer, so that an article finally sold, after passing through five stages or processes, will have borne tax five times, each transaction after the first including the price and also, of course, the tax on preceding transactions. In this way the tax, although levied at a low rate, accumulates until the total tax on the final selling price may be anything from three to six times the amount of the nominal rate.

The third characteristic of the tax is that it is an indirect tax which is intended to be finally borne by the ultimate home consumer. It follows that, in general, a turnover tax cannot, save in exceptional conditions, be levied upon foreigners, and further, that the tax, in so far as it falls upon goods to be exported, must either be remitted or must fall, contrary to the intention mentioned, upon the exporter.

Broadly speaking, therefore, a turnover tax may be defined as an *ad valorem* tax, imposed by way of a fixed percentage upon the price or value of:—

- (a) Every sale of goods, except sales of capital assets, falling within the broad category of investments, and export sales;
- (b) Every passage of goods, while in the same ownership, from one defined stage of production to another;
- (c) Every service rendered, except those rendered by employed persons and those rendered by central or local governmental authorities; and
- (d) Every import of goods.

*Exemption of Exports.*—As a turnover tax is intended to be a consumption tax, capital investment sales are only excluded from its scope because they are not consumable. A turnover tax cannot normally be made to fall upon foreign consumers, and for this reason most of the taxes in force provide for the exemption of exports. If no provision for exemption is made the total tax falling upon exports must rest upon the exporter and as a competitor in world markets, where price is determined by the competition of foreign producers, he is badly handicapped. In this connection *entrepôt* trade deserves special mention, as the imposition of a turnover tax on the gross values of goods entering a country in the course of that trade would, if imposed on the foreign vendors, almost immediately drive such trade to other countries, or, alternatively, if the tax is left as a burden on the domestic traders concerned, it would so penalise them as to make the business unprofitable.

*The Case of Vertical Combines.*—The condition that the tax should apply to every passage of goods while in the same ownership, from one defined stage of production to another, is essential if equality is to be preserved between different tax-payers and different forms of business organisation. While theoretically essential, in practice such a provision necessarily gives rise to grave difficulties. The movement towards large scale organisations in which two or more, or all of the many processes affecting any defined class of goods are carried out within the ambit of one concern, has become of such importance that, on the one hand, nothing should be done to check the economies and wealth-producing capacities of such organisations, and on the other hand, nothing should be done which should give them a striking differential advantage over their competitors through the operation of a turnover tax. In order, therefore, to preserve equality in taxation it will be necessary, in the case of combines, to assess the tax on an estimated turnover for the various stages of manufacture so combined, in order that the tax levied on the final finished product should be the same as though that product had passed through the hands of a normal number of concerns.

*Inclusion of "Services."*—The inclusion of services within the scope of the tax is also essential. The retail price of coal consists almost entirely of the remuneration of the services of the persons who have won it, transported it and distributed it, including in those services those rendered by capital, management and labour. Moreover the supply of goods and services is almost inextricably mixed. The dentist supplies much service with one or two false teeth. The watchmaker does the same when he provides and fits a new main spring to a watch. In practice it is impossible to sever the price of services from the price of goods when they are simultaneously provided at a single inclusive price. Finally, to exclude services would cut deeply into the productivity of the tax. On the other hand, the services of employed persons, remunerated by salaries or wages, are normally excluded from the scope of a turnover tax, because the employee is normally not able to pass on the burden of the tax. If he shifts it at all he can only do so back on his employer and in that case the employer would shift the burden again by loading it on to the price of his goods or services, and the cumulative character of the tax would be greatly increased. Similar reasons attend the normal exclusion from the scope of the tax of services of central and local governmental authorities. As the tax is of the nature of a general excise imposed upon every business transaction within the country and accordingly upon all commodities originating within the country, it follows that all goods imported must be brought within the scope of the tax. Accordingly, a turnover tax involves general customs taxation covering every article within the scope of the turnover tax.

*Exemptions for Food.*—Nothing in the principle of a turnover tax calls in theory for the exemption of food, and as the bulk of most nations consists of the working classes whose main expenditure is upon food, the exemption of food from the turnover tax at once makes an enormous inroad into the universality and therefore into the yield of the tax. Nevertheless the objectionable character of a general sales tax extending to food has led in most cases to wide exemptions in favour of essential foods. In practice this exemption necessarily gives rise to considerable anomalies and inequalities.

*Conclusions.*—To many minds a turnover tax is most attractive. This springs mainly from the universality of the tax and its cumulative nature which permit of a very low rate of tax, combined with a substantial yield. Because the rate is small it is always argued that it will not be noticed, but it enters insidiously into every phase and item of expenditure and in such a manner as to take no account whatsoever of ability to pay. Accordingly, a turnover tax offends against this great modern principle of taxation because the working classes constitute the bulk of every nation, and because their aggregate income (and expenditure), notwithstanding the smallness of the individual income, accounts nearly always for more than half the total of the national income.

A turnover tax falls with the greatest weight on persons whose ability to bear it is least. If services are excluded from the scope

of the tax this inequality is aggregated inasmuch as a considerable part of the expenditure of the richer classes consists of expenditure on services. It is notably in this connection that turnover taxes in one form or another have been adopted widely on the continent of Europe, where direct taxation according to the principle of ability to pay is least favoured, and that on the contrary they find little or no favour among Anglo-Saxon communities where direct taxation grows more strongly in favour. By its universality a turnover tax tends to enter into the cost of production of all goods and therefore to raise the costs of the marginal producer whose influence on price is almost dominant. For this reason a turnover tax is utterly unsuited to any nation which has a large international trade, or which carries on from centres located within its own boundary large manufacturing, commercial or financial business in other countries.

**TUTANKHAMÜN** (see 9.84), or, as he was originally called, Tutankhaten, must have ascended the Egyptian throne shortly after 1358 B.C. He had married Ankhesenpaaten, the third daughter of Akhenaten, and thus, on the death of Akhenaten's ephemeral successor, Sakere, who had married the second daughter, he became heir to the throne. The highest date as yet known in his reign is the sixth year, and as the body found in his tomb is said to be that of a youth of about 18 he must have been a child at his accession, and a puppet in the hands of older men, chief

among whom, doubtless, was the priest Ay, his eventual successor. Presumably he reigned at first in the new city of Akhetaten, but his advisers must already have seen that Atenism, the cult of the sun's disk, established by his father-in-law, was doomed, and that a compromise with the powerful priesthood of Amun was inevitable, for even at Til el-Amarnah itself we find grave-stelae bearing the names of Amun and other orthodox gods. Accordingly he moved back to Thebes, the old capital, with his court, changed his name from Tutankhaten "Living Image of the Disk" to Tutankhamün "Living Image of Amun," restored the names of the old Egyptian gods which Akhenaten had chiselled out on the monuments and made a formal profession of orthodoxy by celebrating the festival of Opet, a ceremony connected with the worship of Amun.

Apparently, despite the neglect of foreign affairs under Akhenaten, Egypt still retained the province of Nubia, for a scene in the tomb of one Huy, viceroy of Nubia, shows the king receiving the Nubian tribute. Another scene shows the reception of the "tribute of Retenu," i.e., of Syria-Palestine. Unless this scene be a mere pleasant fiction, which is hardly likely, it indicates that the allegiance of Syria had not been quite so completely lost under Akhenaten as has been generally supposed. The king's tomb in Thebes has up to 1926 made no contribution to the history of his reign.

**UGANDA** (see 27.557) has an area of about 110,300 sq. m., including 16,169 sq. m. of water. The population in 1925 was estimated at 3,145,000. There were 1,451 Europeans and 7,229 Asiatics (mainly Indians). In 1919 Europeans numbered 847 and Asiatics 3,516. Since 1920 Uganda has become one of the main sources of the supply of cotton in the British Empire.

**Frontier Questions.**—Territorial changes made in 1912 gave the western shores of Lake Albert to the Belgian Congo, while Kizegi, a highland region containing some of the peaks of the Mfumbiro volcanoes, was added to Uganda (partly by transfer from German East Africa). In 1914 the most northern part of the protectorate was placed under the administration of the Anglo-Egyptian Sudan, whose authority was extended south to Nimule, the point where navigation on the Nile from Khartum ends. In return, the Sudan surrendered to Uganda some 4,000 sq. m. west of the Nile, an area which has been part of the Lado Enclave (see 16.60). In 1922 the Didinga district east of the Nile, was taken over by the Sudan. The whole frontier region towards Abyssinia was in an unsettled condition. Here for years Abyssinians, Turkana and Somalis carried on a gun-running trade and made raids on peaceful tribes. To gain a better control of the people and pending a readjustment of the frontier, the Kenya Govt. took over from the authorities in Uganda the administration of the Rudolf Province.

**Social Conditions.**—Christianity and Western civilisation increasingly made their influence manifest, while material prosperity brought new problems. Uganda being, however, a "black man's country," there was no clash between European and African interests. Officials and missionaries continued to play a leading part in the evolution of the people, and they were backed up by the native administration, which has a large degree of autonomy. By 1926 over a third of the natives professed Christianity, including the bulk of the Buganda, the most important tribe. Daudi Chwa, the Kabaka (King) of Buganda, who attained his majority on Aug. 8 1914 and was created a K.C.M.G. in 1925, was an enlightened ruler. He and his Prime Minister, Sir Apolo Kagwa, were foremost in giving aid to the British in the World War. Other rulers and tribes were equally willing, and by supplying 10,000 soldiers, a native medical corps and over 160,000 carriers Uganda helped substantially in the campaign against the Germans in East Africa.

The country suffered from a severe famine in 1919 and from the general trade depression in 1921-2. But it quickly recovered. In cultivating cotton, an industry entirely in their hands, the natives found an easy method of acquiring wealth; a fact not without danger and adversely affecting the labour supply for other work. However, there was steady growth in education and a power of adaptability to new conditions was clearly noticeable. A government Technical school for natives was opened in 1922. In 1924 its scope was extended to include higher education. Otherwise education was in the hands of the missionary societies. At a critical period of development Uganda owed much to the wise guidance of Sir R. T. Coryndon, governor from Feb. 1918 to Sept. 1922. During this period a (nominated) Legislative Council was created. It met first in 1921.

**Cotton and other Crops.**—A beginning in the export of cotton was made in 1904-5 when 300 to 400 bales were produced. By 1912-3 the output had reached 50,000 bales. The War caused a set-back in production, but by 1922-3 the yield was 93,000 bales and in 1924-5 was over 200,000 bales. Some two-thirds of the cotton is grown in the Eastern Province, between Lake Keoga and Mount Elgon. A railway 61 m. long from Tinja (by the Ripon Falls) to Namasagala, the first navigable point on the Nile, was opened in 1912. It is known as the Busoga Railway. To give the cotton-growing district communication with Mombasa port the building of a railway from the Kenya end was begun in Dec. 1921. Branching from the Kenya and Uganda Rail-

way at Nakuru, it is some 320 m. long, of which 165 m. are in Uganda, where a junction is effected with the Busoga Railway. The Uganda section of the line was begun in 1925. By 1926 the area under cotton was over 600,000 ac. while the area suitable for cotton, largely served by the new railway, many times greater.

Coffee ranks second among the crops of the protectorate and is grown chiefly on European plantations. The cultivation of the sugar-cane has been developed. Chillies, oil seeds and rubber are other products. Cattle are plentiful, and there are valuable timber areas. Gold occurs over a long stretch of the Kafu river.

**Trade and Revenue.**—In the process of development imports for many years largely exceeded exports. The figures for 1910-1 were imports £431,000, exports, £337,000. In 1916-7 imports were £866,000 and exports £702,000. In 1917 the Customs were amalgamated with those of British East Africa (Kenya Colony) and since then only net statistics of exports are available. It was soon obvious, however, that exports had become of higher value than imports. In 1918-9 exports were £1,247,000. In 1920, owing mainly to inflated prices they were valued at over £4,250,000; in 1923, with more normal conditions, at £2,393,000. In 1924 exports had reached a value of £3,897,000, while that of imported merchandise was put at £1,975,000. Of the 1924 exports cotton accounted for £3,486,000, cotton seed for £106,000 and coffee for £167,000. Cotton goods, machinery and vehicles (including motor cars and cycles) are the principal imports.

Since 1915-6 the protectorate has been financially self-supporting. In that year revenue was £287,000 and expenditure £285,000. In 1924 the figures were, revenue £1,239,000; expenditure £918,000. The chief sources of revenue are poll taxes (over £400,000 in 1924); customs, a cotton tax, trading licences and land rents.

**UHDE, FRITZ KARL HERMANN VON** (1848-1911), German painter (see 27.563), died at Munich Feb. 25 1911.

**UKRAINE** (see 27.564).—The Ukrainian Socialist Soviet Republic is a constituent State of the Union of Socialist Soviet Republics (see RUSSIA). It comprises the south-western area of what was formerly European Russia, less the territories ceded to Poland, and Bessarabia, the union of which with Rumania was finally sanctioned by the Allied and Associated Powers in a treaty signed at Paris Oct. 28 1920.<sup>1</sup>

**Area and Population.**—The Republic covers an area of 446,400 sq. km. (3,176,567 sq. versts), and is divided into nine governments and the Moldavian Socialist Soviet Republic. The population (1924) was 27,168,962, of which just over 22,000,000 were engaged in rural occupations. These figures represented 2.1% of the area of the Union and 19.4% of its population (1924). A test census carried out in two governments during 1920 revealed a decrease in the population since 1914 of about 11%. Kharkov is the capital (population 311,525) and the other large towns are Kiev (435,060) and Odessa (316,740).

**Political History.**—The Ukraine formed an integral part of the Russian Empire until 1917. When however the Provisional Govt. was established in Petrograd in March 1917, a Ukrainian deputation waited on it in the following month to demand autonomy for their country, and on April 19 the first Ukrainian National Congress met at Kiev to elect a Council of Government (Rada). In June this body assumed the control of

<sup>1</sup> This treaty was not ratified by Italy and Japan.

Ukrainian affairs, and in Aug. the Provisional Govt. of Russia recognised the autonomy of the Ukraine. Contemporaneously with the Bolshevik revolution in Petrograd the Rada proclaimed a People's Republic (Nov. 20 1917). Negotiations between the Rada and the Russian Soviet Govt. took place in Dec. and the former sent delegates to the Peace Conference at Brest-Litovsk, who were duly recognised by the Central Powers. On Dec. 26 the first all-Ukrainian Congress of Soviets met at Kharkov. In Jan. 1918 relations between the Russian Soviet and the Rada were broken off, and the latter proclaimed its complete independence. Bolshevik troops invaded the Ukraine and in March the Rada appealed to the Central Powers against the Moscow Government.

Meanwhile the Ukrainian delegates at Brest-Litovsk had concluded a peace with the Central Powers (Feb. 9 and 11 1918) under which, *inter alia*, the frontiers of the Republic were delimited. By the end of April German and Austrian troops had occupied the Ukraine and established a military dictatorship under Hetman Skoropadski, and early in May an armistice with Soviet Russia was proclaimed, followed in the same month by definite peace negotiations. Soon after the peasants rose against the German administration and at the beginning of June held a Peasants' congress at Kiev demanding the re-establishment of the People's Republic, and on July 30 the German Governor, Von Eichorn, was assassinated. In Nov., Petlura, a member of the former Rada, began operations against Skoropadski, whom he overthrew in Dec., and established a Directory composed of himself and Vinnichenko, which proclaimed the union of the Ukraine with the West Ukrainian (East Galician) Republic. Towards the end of the month Petlura occupied Kiev, but in Feb. 1919 a Bolshevik rising forced him to retire to East Galicia.

On March 1 the second Ukrainian Congress of Soviets met. In their efforts to support anti-Bolshevik operations the French had first bombarded and then occupied Odessa in Nov. 1918, but early in April Bolshevik risings and the advance of the Red Army forced them to evacuate the port, and it fell into the hands of the Soviet troops. In June 1919, however, General Denikin's forces captured Kharkov, and in Aug. overthrew the Second Ukrainian Soviet Government. But the Soviet forces in the Ukraine regained the ascendancy with the capture of Kharkov and Kiev in Dec., and of Odessa in Feb. 1920, whereupon a (third) Ukrainian Soviet Republic was established. Irregular warfare continued for some time and large portions of the Ukraine were occupied by Petlura's and the Polish troops in May 1920, being again expelled when the Russian army took the offensive in July (*see* RUSSIA). By the treaty of Riga (Oct. 12 1920 and March 18 1921) Poland and Russia recognised the independence of the Ukraine. On Dec. 28 1920 a Russo-Ukrainian treaty was signed defining relations between the two Soviet Republics.

During 1921 the Ukrainian Socialist Soviet Republic signed separate treaties with Georgia (Jan. 31), Lithuania (Feb. 14), Latvia (Aug. 3), Estonia (Nov. 25) and Italy (Dec. 27); and also, in conjunction with The Russian Socialist Federated Soviet Republic, with Austria (Dec. 7). In 1922 a treaty with Turkey was signed (Jan. 2) and, again in conjunction with the R.S.F.S.R., a trade agreement with Czechoslovakia (June 5). On July 6 1923 the constitution of the Union of Socialist Soviet Republics was adopted, of which the Ukraine became a constituent member. In Sept. 1924 the autonomous Moldavian Socialist Soviet Republic was formed as part of the Ukraine.

**Natural Resources.**—The Ukraine lies almost entirely in the great steppe belt, and the greater part of the soil is the very fertile black earth. The chief crops are wheat, rye, millet and maize; the area under grain cultivation in 1924 was 20,099,000 desyatins and the crop 747,000,000 poods. Flax and sugar cane are also grown, and fruit trees are abundant. The inhabitants breed the big Tcherkess cattle which are used both for plough and in harness.

The Donets basin, which is the most highly developed (though not the largest) coal field in the Union, lies within the territory of the Ukrainian S.S.R. The district suffered severely during the civil war; the output, which was 1,544,000,000 poods in 1913, fell to 273,000,000 in 1920 and for 1925 was estimated at a little over 600,000,000 poods. Before the War 90% of the Russian coal output

came from the Donets; in 1924, 78%. This area also contains the largest anthracite reserves in the world, and deposits of cinnabar from which mercury is obtained. Rock salt is mined on the edges of the Don ridge. There are large iron deposits at Krivoi Rog, estimated at 200,000,000 tons of ore with an average yield of 62-67% of iron, 9% of silica and .03 to .06% of phosphorus. The annual output in 1925 was about 250,000 tons compared with 6,600,000 tons in 1913. There are also manganese deposits at Ekaterinoslav. The principal metal industrial centres in the Ukraine are at Yusovka (in the Donets), Kharkov, Mariupol, Ekaterinoslav and Nikolaiev. Chemical works exist in the Donets basin, agricultural machinery and hemp factories at Odessa, sugar refineries in the Kiev province, while coopering and pottery are well-developed village industries.

**Communications.**—There are two main lines from Moscow, one through Kharkov, running down to Sevastopol in the Crimea (which does not form part of the Ukraine but is an autonomous Socialist Soviet Republic in the R.S.F.S.R.); the other through Kiev to Odessa. A main transverse line runs through Kiev and Kharkov to Rostov, while branch lines from the Odessa line link up Kiev with Warsaw and Lemberg. Subsidiary lines link up the more important towns, but though the mileage-area ratio is higher in the Ukraine than in the rest of the Union, the transport system, unsupported by any adequate roads, and further hampered by shortage of rolling-stock, is quite insufficient to meet the requirement of agriculture and industry. Kharkov is connected by regular air services with Moscow, Kiev and Odessa. The principal seaport is Odessa, whence comparatively regular services are maintained with Constantinople and with other Black Sea ports. The smaller ports of Nikolaiev, Berdjansk, Mariupol and Taganrog are principally used for coastal trade.

**Education.**—There are numerous schools throughout the whole of the Ukraine, and 38 institutions of quasi-university standing, of which nine are at Kharkov, nine at Kiev and seven at Odessa. (*See* RUSSIA.)

**UNAMUNO, MIGUEL DE** (1864- ), Spanish scholar and man of letters, was born at Bilbao Sept. 29 1864, and in 1892 was appointed to the chair of Greek language and literature at Salamanca University. His mystical philosophy has exercised a great influence on Spanish-speaking peoples, and his imaginative work in prose and verse is also highly appraised. Towards the end of his academic career he began actively to participate in politics. This brought him into conflict with the military directorate and in 1924 he was exiled to the Canary Islands. Later, he refused to accept the amnesty granted and took up his residence in Paris. As a consequence he was dismissed from his professorship. His most characteristic work is *El Sentimiento Trágico de la Vida en los hombres y en los pueblos* (1913) translated into English as *The Tragic Sense of Life in men and in peoples* (1921).

**UNDEN, OSTEN** (1886- ), Swedish politician, became professor of civil law at the University of Uppsala in 1917. Unden, who was a Social-democrat, became a minister without portfolio in the Eden Cabinet from 1917 until 1920, and minister of justice in the first Branting Cabinet in 1920. From 1920 to 1924 he was the expert on international law to the Swedish Foreign Office; and a member of the Swedish delegation at the Assembly of the League of Nations from 1921 and also at the Genoa and Hague Conferences, 1922. He became Foreign Minister in Branting's third Ministry in 1924 and after the latter's death in 1925 Unden succeeded him on the Council of the League of Nations. He was especially prominent at the special session of the Assembly held in March 1926, when he opposed the election of any other country than Germany to a permanent seat on the council.

**UNDERWOOD, OSCAR WILDER** (1862- ), American politician, was born at Louisville, Ky., May 6 1862. He studied at the University of Virginia (1881-4), was admitted to the bar in 1884, and practised law thereafter in Birmingham, Alabama. From 1895 to 1915 he was a member from Alabama of the National House of Representatives, and during his last two years chairman of the committee on ways and means. After the Democrats came into power in 1913 he had a large share in framing the tariff bill passed the same year. In 1914 he opposed the Panama Canal Tolls Repeal Bill, but supported the resolution authorising the President to use armed force in Mexico. He was opposed to the woman suffrage amendment to the Federal Constitution, holding that the question was a state issue. He also opposed the national prohibition amendment. In 1914 he was elected to the U.S. Senate, and in 1920 re-elected. In 1919 he favoured the anti-strike clause of the Cummins rail-

way bill. A strong supporter of the Peace Treaty of Versailles, in Dec. 1919 he offered a resolution in the Senate providing that the president of the Senate should appoint a committee of 10 senators to work out some acceptable plan for adopting the Peace Treaty; but this was blocked by Senator Lodge. In April 1920 he was chosen Democratic leader in the Senate. He was a U.S. delegate at the Washington Conference on the Limitation of Armaments which assembled in Nov. 1921. At the Democratic National Convention held in New York City, June 1924, Senator Underwood was an unsuccessful candidate for the presidential nomination.

**UNDERWRITING:** see INSURANCE.

**UNDSET, SIGRID** (1882– ), Norwegian author, was born at Kallundborg, Denmark, on May 20 1882. After completing her studies at the Christiania mercantile college, Mme. Undset entered a city office in 1899 and remained a clerk until 1909. She thus gained an intimate acquaintance with the empty and unenlivened existence of the girls with whom she came into contact, and utilised her experience in her first literary works, initiated in 1907 by *Fru Maria Oulie*. In 1912 she achieved fame by the great Christiania novel, *Jenny* (Eng. trans. 1920), remarkable for its courageous treatment of the erotic problem. After revealing in one of her minor works (1919) the religious crisis in her mind which in 1925 caused her to join the Roman Catholic Church, Mme. Undset published *Kristin Lavransdatter* (1920–22), a remarkable novel of the 14th century, by which she became known to the English-speaking world. Mme. Undset's work shows psychological depth and an ability to appraise the mind and temper of bygone ages, but these qualities are nowhere enlivened by a sense of humour. Her last work, a 13th century novel, *Olav Audunsson*, is stamped by the same qualities.

**UNEMPLOYMENT**<sup>1</sup> (see 27.578).—If every able-bodied man and woman were regarded as an actual or potential worker, the term unemployment would have a larger meaning than is commonly accorded to it. For it would include the withheld productive time and energy of those who figure in censuses as “unoccupied,” the upper and the lower leisured classes, all who manage to live without doing work. But though such a connotation might be sound and serviceable in a general assessment of national economic waste, it would carry us too far away from the set of actual problems conventionally and conveniently grouped under the term Unemployment. That term covers the idleness of those willing and able to work that is attributable to the conditions of the trade or occupation in which they are ordinarily engaged.

Thus defined; unemployment, however, may not be equivalent to waste of productive time on the part of all “unemployed.” For there are occupations that are essentially or “naturally” irregular in the volume of work they require. Such are those dependent upon climatic conditions, or seasonal requirements related to climate or weather. Agriculture, building, fishing, dock labour, are large and important examples. Most of this slackness is in winter, though there are trades, mining for instance, where employment is slacker in summer. Such fluctuations, as with some other trades, for instance printing and dressmaking, where seasonal activities are less directly traceable to climatic causes, run a fairly regular and calculable course. This regularity, indeed, enables a certain amount of inter-trade adjustment to lessen the amount of wasted time. In some countries, as in Belgium and Russia, where the ties between country and town life are closer than in England, agricultural work sensibly relieves the unemployment in town industries. A second trade, chosen as supplementary to the first, strengthens the earning power, and gives the interest of variation to the working life, though in a highly specialised industrial system the possibilities of such adjustments are severely limited, and trade union discipline raises obstacles.

**Reasons for Unemployment.**—There are two other important sources of unemployment in particular trades that cause trouble

by their irregularity and incalculability. They are changes of fashion or taste in the consumer, and inventions or new processes on the productive side of industry. The dressmaking and to a less extent the textile trades are peculiarly prone to sudden violent changes of fashion, while in most luxury trades considerable fluctuations of employment occur from the freaks of taste, often stimulated from the selling side. New materials, new combinations, shapes and colours rapidly acquire prestige, displacing the old and shifting the currents of employment. The spread of luxury among larger sections of a people and the quicker inter-class imitation give larger significance to this item of unemployment. It may, of course, be urged that no net increase of unemployment is thus caused, for the new fashion yields as much employment as the old. But from the social standpoint considerable net waste ensues from such violent fluctuations.

Inventions, involving important changes of technique, especially in labour-saving machinery, are liable to cancel much manual skill and to displace its owners, though they may indirectly enlarge employment by reducing costs and prices, so stimulating demand. An active era of inventions evidently signifies that at any given time many workers are looking out for a new job. If times are good, and industry in general active, they may not remain long unemployed, but in normal times, still more in depressed, they will encounter much difficulty in fitting themselves into a new post.

It is evident that in any changing civilisation, where all these factors of irregularity and uncertainty are operative, some unemployment is inevitable. It is true, as Mr. Charles Booth succinctly stated, that “our modern system of industry will not work without some unemployed margin, some reserve of labour.” But this margin need not be as wide as it is. More mobility of occupation, inter-local and inter-occupational, should be practicable. Better information through employment bureaux and trade union organisations can speed up adjustments, and so help to reduce the percentage at any moment unemployed. But the efficacy of such measure depends largely upon those wider conditions of general trade, which are commonly brought together under the term cyclical fluctuations.

## I. CYCLICAL FLUCTUATIONS

**The Measure of Unemployment.**—But before entering this largest and most controversial field, it will be convenient to consider briefly how far we are able to measure unemployment. There are two sources of information in Britain, the trade union returns of members out of employment (whether in receipt of unemployed benefit or not) and the returns covered by the Unemployment Insurance Acts. Up to 1920 the trade union returns were the largest statistical basis. They were, and are, a very incomplete index of the total volume of unemployment. For the trade unionists included in the returns are usually less than half of the trade unionists in the country, and the latter are only from a third to a half of the industrial manual workers. Although it is part of the policy of trade unions to secure for their members a preference in employment, it is likely that the proportion of unemployed among industrial workers who are non-unionists is rather less than among unionists. For the trade unions are strongly represented in certain trades that are exceedingly liable to trade fluctuations, such as the building, engineering, metal and ship-building trades. Moreover, a trade unionist is far less likely to seek employment in some other trade than his own, or to accept lower wages in his own trade. On the other hand, the great mass of casual labour will bring up the volume of unemployment in the low-organised trades.

These considerations serve to indicate that the returns under the Unemployment Insurance Act of 1911, extended in 1922 to cover some 11,500,000 manual workers, form a better index of the total amount of unemployment. The only large excluded classes are domestic servants, farm labourers and government employees. These classes, however, are so large and, with the exception of sections of farm labourers, so much more regular in their employment, as to cause some exaggeration to appear, if the insurance statistics are taken as a measure of the unem-

<sup>1</sup>As the amount of unemployment in the United States was so small during the period 1910–26 this article does not deal in detail with that country. (Ed. E. B.)

ployment of the working population in the aggregate. When the official figure for unemployment is 10%, the average unemployment for the workers as an aggregate might perhaps be put at 9% or even less.

As an offset, however, against such a tendency to overestimate, the habit of resorting to short time to meet trade slackness must be taken into account. In coal-mining and the textile trades, especially cotton, this practice must considerably reduce the amount of reputed unemployment. At the lowest depth of the depression in Britain, in June 1921, when 2,171,288 workers were applicants for benefit in respect of total unemployment, 832,340 workers claimed benefit for short time.

*Cyclical Unemployment.*—The minor leakages and fluctuations due chiefly to natural causes, or to alterations in methods of work, or of consumption, are so various and so numerous that they may be held to require a certain small percentage of "waiters" as representing the wholesome elasticity of a free progressive economic system. But can the same be said of the larger periodic movements known as trade depressions, which doom a large percentage of the available productive capital and labour to stand idle for a couple of years or more? Are we to regard

ordinary cycles, it is evident that the War and post War inflation, practised in different forms and measures by almost all European Govts. and the consequent collapse of exchange and internal monetary values, were disturbing factors of prime importance. While inflation exercised an immediately stimulating influence on internal trade by encouraging expenditure, and upon export trade by means of an artificial cheapening of production, the consequent damages to confidence and credit, the ruin of large sections of the middle-classes, the difficulty of the import trade and the scarcity and dearness of working capital, were main contributions to the long depression.

Closely connected with this financial disease was the sabotage of commercial relations, accompanied by high tariffs and embargoes upon the movement of goods and investments, and the breaking up of the economic unity of the Austro-Hungarian empire. The virtual isolation of Russia from free economic intercourse with the outside world brought a serious curtailment of foods and raw materials for other countries, and a corresponding reduction of manufacturing exports.

New difficulties arose between town and country, due to bad money, creating food shortages, depressed wages and efficiency

FIG. 1.—Graph showing the percentage of unemployed in Great Britain and Northern Ireland, among workpeople insured against unemployment (broken line) and members of certain trade unions (continuous line).

(Ministry of Labour Gazette.)

these large fluctuations as inevitable, or possibly desirable? First, a word as to the size of these fluctuations. Before the War the annual averages of unemployment swung between about 2½% and 7½%, leaving an implication that our system for its free-working requires an average unemployed margin of some 5%, half of it representing the minor trade changes and leakages to which we have referred, half forming a reserve of labour to enable expansion to take place in good times. But War and post-War experience show a far more violent fluctuation. For, whereas the figure for 1918 was 0.8 and for 1919 2.4, the depression which set in at the close of 1920 reached by June 1921 the extraordinary figure of 23.1%, and the trade union average for 1921 was 15.3, for 1922, 15.4.

Two other general tendencies may be noted. The larger intercourse between industrially developed countries since 1875 has made these ebbs and flows of trade more simultaneous. The "boom" years 1873, 1874, 1900, were common to all industrial nations, so was the collapse of later 1907. The other tendency is the shortening of the cycle. Before the seventies of last century there was something like a 10 years' rhythm. Since then the periods have shortened, the years of maximum trade activity being 1873, 1882, 1890, 1900, 1907 and 1913. The post-War situation caused some disturbance of both these tendencies. "Japan began to feel the effect of trade depression in 1919 when trade in Great Britain was in full swing. In 1921 Germany was expanding her industries rapidly, while Great Britain was in the throes of the depression. Again, in 1923 economic conditions in the United States showed a very striking recovery, and indeed she attained in the spring a condition of record trade activity." (Hon. J. J. Astor, *Is Unemployment Inevitable?*, p. 11).

*The Post-War Depression.*—Before discussing the causes and remedies of normal cyclical unemployment, it will be well to deal briefly with the peculiarities of the post-War depression, which alike in its causation and its character is abnormal. Without prejudging the question of the part played by finance in

among industrial workers. Political disturbances, accompanied by strikes and labour difficulties in most countries, were a factor in low production. More important in Britain and other ex-belligerent industrial countries was the collapse of industries overstimulated for war-production whose excessive plant and labour could not be adapted readily to useful work in the after-War world. The huge depression in the iron and steel, engineering and ship-building trades, as in the mining, was largely attributable to this cause.

Monetary disturbances, commercial obstacles, industrial dislocation, revolutions and sporadic warfare have thus contributed towards a trade depression unique in its character and distribution as well as unprecedented in its magnitude and duration. These different causes operated at different times and with different stresses in the various countries. In every country there was a striking coincidence between the fluctuations of prices and of employment. When prices fell unemployment rose, and vice versa. The countries not directly implicated in the War suffered as violent fluctuations as the ex-belligerent countries. The unemployment figure in each of the Scandinavian countries (with the exception of Finland) was higher in the later part of 1921 and the opening of 1922 than the British highest figure. Switzerland touched 25% in Jan. 1922 and Belgium 32.3% in May 1921.

In Germany and Austria inflation postponed the trouble until monetary reform was carried out; then came reaction and widespread unemployment. In general the internal monetary policy played a more determinant part than the restriction of the export trade, re-absorption of the fighting forces, political animosities, tariffs or any of the other disturbing factors of the post-War world. This would seem to apply even to Great Britain, where certain of the principal export trades have been the heaviest sufferers. For "most of the trades in question are also essentially producers of capital goods which invariably suffer worst during depression, even though they produce for home consumption only. They are also the trades which were over-expanded during

FIG. 2.—Graph showing the trend of unemployment in certain countries. (Based on trade union returns.)  
(Ministry of Labour Gazette.)

the War and for the production of which there is now neither home nor foreign demand on the same scale as before" (*Unemployment, 1920, 1923*, p. 113: International Labour Office).

But though fresh light has thus been shed upon some aspects of our more normal economic life, especially upon its financial side, the war-origin of these phenomena disqualifies this depression from figuring as a safe study for those who seek to understand the more regular cyclical movements of industry.

## II. THEORIES OF CYCLICAL UNEMPLOYMENT

*The Physical Theory.*—For convenience the explanations of the origin and causation of cyclical unemployment may be placed in five classes, not indeed mutually exclusive but presenting different aspects and starting points.

The first may be termed the physical theory, dealing with the meteorological factor in trade fluctuation, which first came to the attention of economists by the work of Prof. W. S. Jevons, who claimed to establish a connection of the appearance of sun spots with climatic conditions affecting harvests, and thereby the productivity and purchasing power of the world. Though later astronomical records give no support to the sun-spot theory, attempts have been made by Mr. H. S. Jevons and Sir W. H. Beveridge to relate climatic variations with food supplies and general trade. But though there is nothing inherently improbable in such correlations, the case presented in statistics is not convincing, even if allowance is made for what may be called accidental lags. The restricted scale of the crop-records, both as to areas and kinds, the dubious reliability of the earlier records, the combination of various minor and major waves, the overlapping of supplies from year to year, especially in modern times, the limited effect which such crop variations as are shown could exercise upon the total industrial activity, deprive this class of explanation from any claim to more than a minor speculative interest.

That variations in harvests, if they are considerable and widespread, will exercise some influence upon industrial output, transport and employment, is undeniable. If foodstuffs and raw materials are produced in diminished quantities at higher selling prices, the processes which work them up, carry and distribute them, will be reduced in the employment they afford. Not, however, necessarily to an extent corresponding with the crop-shortage. The effect will be greater when trade is very active than when sluggish and over-stocked. The argument, often stressed, that in bad seasons the agricultural classes, having less spending power, will reduce their purchases of other goods and services, and so spread depression, cannot be accepted without qualifications. If it were true, as is sometimes held (*e.g.*, Hull,

*Industrial Depressions*, p. 45, etc.) that small crops often bring in as much money as big crops, the argument would of course collapse. But the varying elasticity of demand for different articles makes it pretty certain that a widespread bad harvest has some effect in reducing the purchasing power of the rural population. Moreover, the rise in food-prices will reduce the expenditure of the industrial classes upon other goods, causing a total shrinkage of demand that must affect employment. But having regard to better crop information, quicker and more reliable transport over wide areas, improved finance for stimulating, moving and marketing raw products, better instruments for storage and preservation, climatic causes ought to play a constantly diminishing part in cyclical fluctuations.

*The Accidental Theory.*—Under this head may be placed those who, discarding all general views of causation, impute trade depressions to a variety of unconnected occurrences, sometimes political, such as wars and revolutions, or natural, such as droughts or floods, or business, such as the collapse of active railroad enterprise, or financial, such as a banking crisis. Local troubles, thus brought about, spread by contagion or infection, until they have depressed the entire industry and commerce of large sections of the world. It is undeniable that one or more of such injurious occurrences, a bad monsoon, a war or revolution, a "Black Friday" or an Australian bank collapse, may and does play quite a distinguishable part in precipitating a crisis of trade and ushering in a period of depression. But most of these events belong to human conduct and are due to economic forces wider and longer in their operation than the catastrophic acts which figure as immediate causes of financial or industrial trouble. There is sufficient regularity in these cyclical fluctuations to enable us to dismiss as inadequate the view that regards them as pure accidents.

*The Psychological Factor.*—Business action is so dependent upon beliefs and feelings that some economists use language implying that industrial prosperity and depression are little else than reflections of a rhythmic movement of confidence and dejection in the minds of men. This psychological rhythm, operating upon industry through credit (the financial index of confidence) they regard not merely as an accompaniment and agent, but as the chief efficient cause of industrial fluctuations. Starting with the assumption that the business mind is by nature prone to these alternating elations and depressions, and that they are quickly and easily communicated by business leaders to the rank and file, the theory of independent psychological causation becomes plausible. In times of rising confidence business men seek to borrow freely from the banks, and the investing public to extend their profitable business operations. Bankers,

sharing the confidence of their customers, make large advances upon reasonable terms at such times, and new capital is forthcoming to extend existing businesses and open new ones. This wave of confidence having spent its force in thus stimulating credit and industrial activity, begins to subside, credits are restricted or called in, because of a belief that trade is going down, and this belief and restriction are the means of reducing the volume of commerce and contracting business operations. Thus a depression is brought about "because of their unbelief."

*Credit Fluctuations.*—This separate presentation of the psychological movement, however, is uncommon. The connection of these fears, hopes and illusions with "credit" is so close and obvious that it is here we must seek for the connection between the moral and material aspects of a cyclical fluctuation. If everyone bought with his own money alone, business operations, though more restricted and less productive, would be subject to smaller variations in volume and value. The worth of the credit and investment systems is that they permit the rapid seizure of opportunities for profitable expansion of industrial activity. The concrete productive forces of land, capital and labour are thus handled to greater advantage.

*Courses of the Cycle.*—How credit actually operates in the cyclical movement is best seen by following the general course which such a cycle takes. In tracing this course it is well to begin from the start of a trade revival. When a depression with low production, low prices, profits and employment, has continued for some time, the excessive stocks which, because they could not get sold fast enough, congested the wholesale markets at the beginning of the depression and brought prices down, show signs of approaching depletion. It becomes evident that the current rate of production will soon be inadequate to meet the effective demand at the present low level of prices, and that, to stimulate production, prices are going to rise. Merchants handling wholesale trade are usually most sensitive to the situation, and are the first to take action. Anticipating an early expansion of sales at higher prices, they seek to make contracts with manufacturers and other producers for future delivery of materials and goods upon a larger scale.

These producing firms seek to replenish their lowered stocks of raw materials, fuel, etc., to improve and enlarge their plant and to take on more labour. The fundamental and instrumental industries such as mining, iron and steel, engineering and ship-building, where depression and unemployment have been deepest, must set to work at once in order to make timely provision for the renewed activity in the later stages of production. Merchants, manufacturers and makers of instrumental capital must all seek the assistance of banks for the means of making these expansions. Since bank customers during a depression find a difficulty in getting safe or lucrative investments for their savings, bank deposits are swollen, and partly from this source, partly from the banks' own resources, the credit required, both for increased working capital by short loans, and for more permanent investment, is obtainable from the banks and the investing public.

The limits set upon such expansion are slow to appear. For, in the earlier stages of the process, the well-founded conviction of bankers that there is a genuine revival of trade which permits them with safety and profit to make advances to customers, and the possession of large unused cash reserves, seem to make liberal credits a good banking policy. Thus business men are able to go ahead with increased production, absorbing the capital and labour that had lain unemployed, and enlarging the volume of output and sales at prices which yield an increasing margin of profit. But, when the movement has gone a certain way, two things happen. As soon as the productive power of industry, especially in the great machine trades, has been in full play for a little time, merchants begin to realise that they can get quicker deliveries on easier terms than when the revival began, and as prices are still high and profits large, they become speculative holders of large supplies, applying to their banks for credit to assist them in this policy. The confidence which a genuine revival has inspired, and the belief that prices will go higher still,

induce the banks to aid and abet what is in reality a speculative boom in which prices for a time may rise higher than the level to which the industrial boom has brought them. It is now generally recognised by financial experts that insufficient knowledge of actual trade conditions is largely responsible for carrying the cyclical wave of prices to an excessive height by this undue use of credit.

*Wages and Prices.*—The other thing that happens is even more crucial in its consequences. In the revival of trade the rise of wages continually lags behind the rise of prices. This means high profits for traders, and no considerable risk for bankers with their large cash reserves. But when the revival has reached its height and prices remain fairly stable at a high level, wages creep up and the workers demand their share of the prosperity. This brings simultaneously a cut in profits, that in some measure weakens the borrowing power of the business man, and a reduction of the bank reserves of currency to meet the weekly demands of the higher wage-bills. As cash reserves are reduced, the banker takes alarm, and, following his customary policy, raises his rates, restricts further credit and calls in loans. This forces business men to realise on their stocks, prices fall with a rush, orders fall off, production slackens and unemployment sets in. The fall of prices, accompanied by a fall in profits and later on in wages, does not stimulate enough increase of demand to check the process of depression. So the circle comes round.

This presentation of the cycle tends to support the view that trade fluctuations are pre-eminently credit cycles, the efficient causation of the movement coming from the money side. There are those who appear to hold that a stronger, clearer-sighted and more disinterested banking policy could stop altogether great trade fluctuations, except so far as they might be due to great natural or political interferences. If bankers, they argue, would rigorously check further emissions of credit to traders when industry had reached its full activity with capital and labour fully employed, the speculative part of the boom with its rocketing of prices would be stopped. Or if, again, they were more cautious in restricting credit later on when the tide was beginning to turn, the collapse of prices and restriction of output which ensued might be avoided. A more judicious and public-spirited bank policy might, at any rate, cut off the peak of the trade curve and maintain a large degree of stability of prices and production. The prime cause of unemployment, according to this diagnosis, is the inelasticity of the modern monetary system.

*The Under-Consumption Theory.*—A fourth school of thought fastens upon under-consumption, or failure of consumption, to keep full pace with the swelling current of production, as the main efficient cause of unemployment. Their argument runs thus: In any economic society, the current condition of the arts of production and standards of consumption will determine, not only how much productive power of capital and labour can be economically employed in the several processes of industry and commerce required for turning out the different sorts of consumable goods in their due proportions, but also how much of the current increase should be applied to taking out consumable goods for consumption, and how much to stimulating the increase of productive capital in the various processes of industry. If too little is expended in the latter way, i.e., if savings are small, then there will be an insufficient provision for a rising standard of living for a larger population in the future. If too much is "saved" and too little "spent," there will come into being a larger amount of productive capital in plant, tools, materials, etc., than is required to turn out the consumable goods that get bought and consumed. Though any individual, or group of people, may save as large a proportion of their income as they like without inconveniencing the economic system, economic society as a whole is restricted in the proportion of the general income that can usefully be saved by the condition of the arts of industry.

In a primitive society very little industrial capital can be utilised: a modern industrial society affords a great scope for saving and investment. But there is always a limit in the pro-

portion of income that can be economically utilised as new capital. If that limit were passed, too much capital being created for the supply of the quantity of consumables that were purchased for consumption, a stoppage of industry would take place, some of the industrial plant standing idle or half-used, with a congestion of unsalable goods accumulated either earlier or later in the processes of production. The actual over-production of consumables, or even capital goods, need not go far; the real mischief will consist in the slowing down of the entire process of production with a stoppage of the worse-equipped or worse-placed plants. As this productive plant slows down or stops, a corresponding body of unemployment is created. Real and money incomes are thus reduced: profits, the main source of industrial savings, shrink, most other business incomes fall, so that the proportion of savings is let down for a time far below the true normal. Spending does not fall proportionately, so that gradually the congestion of the economic machine is released, goods being taken out faster than they are being replaced. Weaker firms during the depression have gone out of business, and little new plant has been created.

When this double process of depleting stocks and letting down plant has gone so far that irreducible consumption is tending to exceed current production so that prices begin to turn upwards, this indication of an approaching revival of trade stimulates merchants and manufacturers to prepare for the revival. That preparation involves primarily a renewed activity in the fundamental and instrumental industries, in order that more manufacturing plant and larger supplies of raw materials may be ready for the expansion in the later processes. The mining, metal, engineering and transport trades, which depression had hit hardest, revive earliest and fastest, for their increased output is a prior condition to full activity in the manufacturing processes. For this process of revival an expansion of bank credit and of currency is a necessary instrument and adjunct, but the efficient causation of the movement does not proceed therefrom.

A variant of this under-consumption theory attributes depression to an over-investment in the instrumental and constructional industries, due to an over-estimation of the intensity of future wants which, operating in the immediate interests of the business classes, restricts consumption by putting an excessive proportion of productive power into industries the consumable fruits of which are long delayed and cannot in fact justify the amount of productive energy directed into them. The position is thus stated by Mr. Denis Robertson:—

Since each new investment, once it is made, will be capable of functioning for a considerable period, the rise in the utility of new constructive goods will often in any case only be temporary; a point will be reached beyond which any further investment would involve a sacrifice of present enjoyment disproportionate to the enjoyment which will be afforded by the new consumable goods which it is proposed to create. In fact, however, owing to the stress of competition, aggravated by the length of time which must elapse before the new instruments projected can be brought into working order, investment is likely to be carried beyond this point. (*Study of Industrial Fluctuation*, p. 240-1).

This view, that an opposition of interests exists between the investing classes on the one hand and the working-class consumers on the other, is reinforced by the writings of Mr. Veblen (see especially *The Engineers and the Price System*), who charges the former with practising a sabotage of industry, by chronic restriction of productivity and output in order to make larger profits out of regulated prices.

*Over-population Theory.*—Neo-Malthusians often explain unemployment as a necessary implication of the tendency of population in certain countries, or in the world, to increase faster than the means of subsistence, or the growth of the fund of capital required for their employment under modern industry. From the assumption that a given area can only support a limited population in employment upon such a standard of living as is required to sustain a family, they argue that in many countries the limit has been passed, and that though there may be other areas capable of bearing larger populations than exist at present, the transfer from over-peopled to under-peopled areas is so much impeded

as to leave in the former a considerable surplus over the normal economic requirements of the labour market. Though for a time in certain favoured lands the pressure of the law of diminishing returns to agriculture may be offset by high productivity of manufacture, the surplus of which may be used to purchase increasing supplies of foods and raw materials from newly developed lands, the difficulties of this economy increase as the more fruitful of the backward countries advance in population and in the development of their own industries.

Moreover, the restrictions of tariffs on the one hand, and free migration on the other, make the natural adjustments more difficult. The World War not only stopped the normal emigration by which congested European countries relieved themselves, but stimulated the erection of new barriers, especially by checking the flow of European labour into the United States. On the other hand, the losses of the War and the lower birth-rate and reduced growth of population signify a considerable reduction in the numbers entering the labour-market in these countries, especially later on when the full force of the lower birth-rate is represented in adult numbers. So far as a reduced population carries with it a better distribution of income, through higher wages, it may, in accordance with the under-consumption theory, stimulate a larger volume of demand and more employment. But statistics do not sustain the view that comparatively sparsely peopled countries like the United States, Canada and Australia, escape periods of unemployment that are as large proportionately as those of thickly peopled Europe. While, therefore, the world volume of employment is evidently increased by mobility of labour, as of capital, from one country to another, retardation of migration cannot be regarded as a major cause of cyclical depressions and unemployment.

### III. REMEDIAL MEASURES

*Commercial Organisation.*—The remedies for unemployment, of course, vary with the different theories of the causation of the trouble. Orthodox economists, attributing it to a combination of unpredictable natural causes and business miscalculations, chiefly rely upon improved organisation of markets, communications and finance, to reduce and alleviate the fluctuations. Even the natural causes can be considerably abated by increasing the dispersed sources of supply, and by better crop hygiene. But their main remedies are fuller and more reliable statistics, better business education, publicity of trade information, sound banking, with its steadying effect upon the minds and methods of business men, and, finally, the more controversial proposition of a willingness of organised labour to assist the recovery of trade by accepting lower wages when prices and profits have fallen. Misapplications of productive power, with their attendant losses and stoppages, could thus be averted. Business men, investors and workers would have the fuller confidence and security which better understanding of all factors in the business situation gives. Planning would be improved, speculation would be more enlightened and greater stability of industry, prices and credit would exist. This view is stated in the following terms by Sir W. H. Beveridge (*Unemployment*, p. 193):—

Unemployment is a question not of the scale of industry but of its organisation, not of the volume of the demand for labour but of its changes and fluctuations. The changes are of several types; trades decay or are revolutionised by new machines. Through these changes particular parts of the labour supply get displaced. Unemployment arises through their difficulty in getting re-absorbed. The fluctuations, also, are of several types; some co-extensive with the economic life of the nation; some peculiar to certain trades; some purely local or individual. To meet these fluctuations—cyclical, seasonal and casual—there are required reserves of labour power. Unemployment arises as the idleness of these reserves between the epochs when they are called into action. The solution of the problem of unemployment must consist, therefore, partly in smoothing individual transitions, partly in diminishing the extent of the reserves required for fluctuation or their intervals of idleness, partly, when this plan can go no further, in seeing that the men of the reserve are properly maintained both in action and out of it. The problem is essentially one of business organisation, of meeting without distress the charges and fluctuations without which industry is not and probably could not be carried on. It is not a problem of increasing

the mere scale of industry. It is not a problem of securing a general balance between the growth of the demand for labour and the growth of the supply—for this general balance is already secured by economic forces—but one of perfecting the adjustment in detail.

**Banking and Currency Control.**—Those who hold trade cycles to be pre-eminently credit cycles seek remedies for depressions and unemployment in a more intelligent control of banking and currency. Since these fluctuations are brought about by price changes, the aim should be to stabilise prices, or at any rate to keep the fluctuations within narrow limits. If any economic events, affecting the supply of goods, tend to raise or lower prices, the supply of money should be increased or diminished so as to compensate for such disturbance. A depression in which capital and labour lay unemployed because prices were too low to cover costs of production should be met by emissions of credit which by raising prices would stimulate industry. These small doses of inflation would, it is contended, enable industry to absorb the unemployed capital and labour, by raising prices to a level which sufficed to yield reasonable rates of wages and profits. Then, when industry was brought into full activity, prices should be stabilised at that level, and a monetary policy devised to keep them stable. Some financial purists, objecting to the inflationary method, would wait for general trade causes to produce a revival and would then apply the stabilising policy.

There are various methods advocated for stabilisation. Some are based on the retention of the gold standard. The volume of currency could be expanded or contracted by increasing or reducing the quantity of gold in the unit of account. This is the essence of Prof. Irving Fisher's proposal of a "compensated dollar." Others would follow an elastic policy of expansion or contraction, operated by a central bank in conjunction with the Government, whereby alterations in the discount rate should be fortified by a selling or purchase of public securities. Others, again, regarding a gold standard as a hampering factor in the situation, would regulate the quantity of credit and currency by exclusive attention to the demands of trade, at any rate for purposes of intranational payments, gold being retained exclusively for purposes of international exchange pending the possible future development of a reliable federation of national banks pursuing an agreed international policy for the emission of credit and currency. (See CURRENCY.)

Various critics of established monetary systems in recent years attribute depressions to the failure of the volume of purchasing power to correspond with the actual or potential volume of goods. All that could be produced could not get sold, because of the lack of money in the hands of would-be purchasers. This is sometimes attributed to the credit system, operated by the "money power" which by financing trade raises costs of production and selling prices to a height greater than the purchasing power distributed among the owners of the factors of production at the various stages. On this view, it is necessary for the State bank, or other money-makers, to provide a supplementary supply of purchasing power in order to furnish adequate markets for all the goods which the economic system could produce.

**Taxation and Income.**—Between the financial doctors and the under-consumptionists there is this common ground, that both find that the reason why goods cannot get produced in bad times is that there is an insufficiency of purchasing power in the hands of the consuming public to buy them at a price covering their costs. But most under-consumptionists attribute this insufficiency to a maldistribution of income. An insufficient proportion of the actual or possible income passes to the classes who would spend most, an excessive proportion to those who would save most. This, as we saw, leads to an attempt to put into concrete shape and activity a larger quantity of capital than can function productively in turning out the volume of consumable goods that can be taken out of the productive system to be consumed. Those who accept this diagnosis find the only valid remedy in measures for a better, or more equal, distribution of income. Measures of taxation devised so as to take rents, excess profits, windfalls and other elements of income that are "surplus," in the sense that they do not evoke productive efforts from the

recipient, and to apply them economically to sound purposes of current public expenditure, make for this better distribution. So do political or non-political actions that raise the proportion which workers take in wages out of the general income of the country. Economists favourable to a socialist or labour policy generally hold that a sound test alike for preventives and remedies for unemployment is the absorption of "surplus" income in wages or in public revenue.

**Palliative Measures.**—The different views of the origin of unemployment affect the attitude of business men, politicians, workers and economists, towards the measures adopted in various countries for the alleviation of the burdens of actual unemployment upon the working classes and the community. Leakage between jobs and other minor wastes may be repaired by employment exchanges where out-of-works may apply for vacant posts. Quick, full and reliable information may here greatly help the mobility of labour. Trade unions, either working with employment exchanges, or on their own account, make it their business to find vacant jobs for their unemployed members. In Great Britain there existed at the close of 1924, 382 employment exchanges, 772 branch employment offices and 324 local employment committees, representing employers, workers and certain other bodies. Where trade conditions are largely of local determination, it may be possible for displaced workers to find a job in some other town or district, or even in some other country. Travelling money is provided by many unions, and in certain continental countries, as in pre-War Germany, relief stations are provided in order to enable unemployed workers to move about in search of work.

Another mode of stopping leakages is a decasualisation policy applied chiefly to certain classes of dock labour, where the inherent irregularities of the trade are intensified by keeping an excessive reserve instead of tightening up the organisation of the trade. Seasonal fluctuations may be similarly remedied by transference from one seasonal trade to another. This is probably applicable only to low-skilled work. "Building, with all the country occupations—harvesting, fruit picking, hopping—on the one hand and the gas-works, the docks and all the exceptional Christmas demand in the Post Office, in shops and elsewhere, offer ample material for a start" (Beveridge, p. 210).

Schools and juvenile employment exchanges can do much to help a better apportionment of young labour among the occupations. At the end of 1924 there were in Britain 140 juvenile advisory committees attached to Employment committees and 145 choice-of-employment committees under local education authorities. Continued education for unemployed boys and girls has made some progress since the War in England, and a beginning has been made in technical or vocational training as a contribution towards improved efficiency of labour and enlarged supply of skilled workers. In Germany vocational guidance has taken on great activity, the number of offices in 1924 being 597, of which two-thirds were working with the employment exchanges.

The Ministry of Labour of Great Britain co-operates with Dominion Governments in finding employment overseas for willing emigrants, though the numbers thus placed are small. There are difficulties on both sides, unemployed workers preferring to await the chance of work at home, and the Dominions exercising a rigorous choice in the personnel of those they admit.

Publicly organised relief works are a device for dealing with unemployment widely adopted in Britain and other countries. In England the unemployment grants committee was established in Dec. 1920, to give financial aid to local authorities in executing "works of public utility designed to secure some measure of relief in districts or in trades suffering from unemployment." The committee operates partly by loans of public money, varying from 50 to 75% of the capital costs of the undertaking; partly by grants amounting to 75% of the wage-bill for unemployed men taken on. Most of the works thus encouraged were dock and harbour extensions, gas, water and electric supply, roadmaking, sewerage works, parks and recreation grounds, construction of public ferries. In addition to the employment

directly afforded by these works, an almost equal amount is provided in factories, etc., for the production of the materials required. During the four and a half years working to June 1925 the estimated capital cost of the approved works was £85,123,737, and the total grants were £68,434,280. The amount of employment thus provided was estimated at 3,181,270 man-months. This policy has conformed to the recommendations of the Minority Report of the Poor Law Commission of 1907 in seeking to even out the total volume of employment by allocating public expenditure as far as possible to periods of depression and unemployment.

**Insurance against Unemployment.**—By far the most effective provision for the unemployed is by insurance. This began when certain trade unions in Britain and Belgium, about the middle of the 19th century, arranged to pay regular allowances to members out of work. This method of provision has grown in various countries, and has been built into the public insurance schemes of more recent times (see INSURANCE, SOCIAL).

There are various outstanding problems in the development of unemployment insurance policy. The widest is concerned with the question whether the basis of insurance should be general<sup>1</sup> or industrial. The latter view is supported on the grounds that each industry is best qualified to deal with its own risks, which, alike in size and origin, differ from those of other industries. The former view stresses the common needs of the unemployed, the difficulty the more fluctuating trades would find in making adequate provision, and the advantages of one instead of many administrative bodies. So far, in countries where compulsory insurance prevails, the general tendency has been towards a single uniform administration, though in the British case certain exceptions are admitted in the 1920 Act. Other difficulties arise as to the interpretation of the "suitable employment" which an unemployed person may not refuse, and of the term "involuntary unemployment" when a strike or lock-out throws out of work members of other trades than that directly affected. How far should insurance cover seasonal and short-time unemployment? A large issue remains, that of the linking up or unification of unemployment with other working class risks in a joint insurance policy. (See TRADE CYCLE.)

Cohen, *Insurance against Unemployment* (1921); J. A. Hobson, *The Economics of Unemployment* (1922); F. Lavington, *The Trade Cycle* (1922); *The Third Winter of Unemployment*, ed. by W. T. Layton (1923); H. Abbat, *The Unclaimed Wealth* (1924); Hon. J. J. Astor, *Is Unemployment Inevitable?* (1924); See also—Ministry of Labour, *Report on National Unemployment Insurance* (1923); International Labour Office, *Unemployment in its National and International Aspects* (1924); and *General Problems of Social Insurance* (1925); *Unemployment Insurance in Great Britain; a Critical Examination* (1925); W. T. Foster and W. Catchings, *Profits* (1925). (J. A. H.)

**UNIONIST PARTY:** see CONSERVATIVE PARTY.

**UNITED KINGDOM OF GREAT BRITAIN AND IRELAND** (see 27.598).—Under the Irish Peace Agreement of 1921, southern Ireland was made a Dominion of the British Commonwealth. The official name of the rest of the British Isles remained the United Kingdom of Great Britain and Ireland, no provision being made by the British Parliament for a change of title, but from 1922 onwards the name of Great Britain and Northern Ireland was much used in official documents. (See GREAT BRITAIN; IRELAND, NORTHERN; IRISH FREE STATE, etc.)

**UNITED STATES, THE** (see 27.612), a federal republic with an area of 3,026,789 sq. m.; and a population 105,710,620 (1920). The estimated population in 1925 was 113,493,720 (U.S. Bureau). The following article opens with a survey of the political

<sup>1</sup> If it is held that the main object of insurance is merely to alleviate the effects of social risks by compensating the sufferers, this would lead to the preference of a general system of insurance against all risks, since they all equally involve the loss of wages or earnings. If it is considered, on the contrary, that insurance should aim essentially at preventing or minimising risks, and compensating the sufferers only when such prevention fails, differentiation according to risk naturally seems preferable (*Employment Insurance*, p. 134, Geneva, 1925).

history of the United States, this being divided into three parts, dealing respectively with the pre-War, the War and the post-War periods. The second section deals with finance and wealth; this is divided into two portions, one discussing the national finances and the other the amount and distribution of the country's wealth and income. The third section is on production, industry and trade, including agriculture, and the fourth is on population. The fifth and concluding section deals with communications. Other subjects affecting the United States are discussed in a number of articles, for instance, those on the various states of the Union, on its large cities and on its universities. The banking system of the U.S. is described under the heading BANKING, and the question of defence is discussed in the articles AIR FORCES; ARMY; NAVY; PACIFIC, etc. Other articles to which reference may be made include EDUCATION; FOOD SUPPLY; INCOME TAX; INSURANCE; MARKETING; PROHIBITION; TRADE UNIONS; WAGES.

## I. POLITICAL HISTORY

**The American Nation.**—The people of the United States were much more conscious of themselves in 1908 than in previous periods, because they had come to recognise the variety of their make-up. In 1910 the total population of the continental United States was 92,000,000. Of these, only 50,000,000 were native whites of native parentage; 13,000,000 were foreign-born, and 19,000,000 others were of foreign-born or mixed parentage. The negroes and Indians together numbered about 10,000,000. Everybody in the United States except the American Indian is an immigrant from some other country or a descendant of an immigrant. The main race groups are: (1) the descendants of the colonists, who were mainly Anglo-Saxons, with some Germans and Scotch-Irish and small elements of other races; (2) descendants of the Europeans who came over in great numbers from 1820 to 1870; (3) the large number of recent immigrants and their children.

In the opening years of the present century the country was not yet aroused to the dangers arising from this mixture of unassimilated races. Few voices were raised against admitting not only western Europeans, whose languages and customs were much like those of the United States, but men and women from east and southeast Europe and from western Asia. The only bar to immigration based on race was the prohibition, since 1888, of Chinese immigration and the practical exclusion of Japanese labourers by a "gentlemen's agreement" with the Japanese Govt. (1907). There was no intelligence qualification, and little effective exclusion of any kind. The undigested load was becoming heavy.

The immigrants were not the only burden on the state. Millions of American-born, many of them descended from the old colonial stock, were poor or ignorant or criminal. The situation was saved by general prosperity, and by the American spirit of cheerfulness and confident waiting for things to come right. Furthermore, out of unpromising conditions had arisen such strong figures as Abraham Lincoln and William McKinley. The American Indians were a small separate race, of only about 250,000. The negroes, about 10,000,000 in number, were unorganised as a race, and were scattered over a large area, mostly in the south. Legally equals of the whites, they were subject to humiliating discriminations, and in north and south alike were held in an inferior social position from which there was no escape.

**Defects in Government.**—The units of American society were held together by a strong, if complicated, democratic government, well fitted to rule a diverse population. The political forms were familiar to every school-boy: (a) A group (in 1910) of 46 states, each with its own government rigidly confined by the traditional principle of "checks and balances" into three departments, legislative, executive, judicial; (b) a widely distributed franchise almost equivalent to universal suffrage for adult males; (c) a belief that the courts were the highest authority, not only as to questions of personal rights and duties, but as to the validity of the laws and acts of the other two departments; (d) local government of city and town, township and county. This combination of governments was expensive; it

was not highly skilled; but it was supported by the conviction of a large part of the population that it was the "best government on earth."

The boast of the United States was its equal opportunity—the pride of the United States was its popular government, in which the will of the people was considered to be the only ultimate force. As a nation, Americans believed that they had, more than any other country in the world, the blessings of personal liberty, of free public education, of sharing in their government, of impartial judges. Everybody was supposed to have a fair chance in life.

In the organisation and conditions of business there could be traced some startling contradictions between the word liberty and the fact. Nominally all kinds of business not prohibited by law were open to all comers in free and honourable competition. In reality, by 1908, a considerable number of both employers and employees were engaged in a combat outside the laws, constant and conscienceless. It was hard for individuals and firms to compete with corporations, and hard for small corporations to compete with large ones. The railways were among the most conspicuous of the large corporations, and they, too, tended to combine into larger and more powerful units. The states could not deal adequately with these powerful bodies because most of the railways and many of the other corporations operated from state to state, and could not be controlled at either end by anything short of federal power.

Political organisations were on nearly the same basis as business companies: they also grew bigger and more powerful and gathered into fewer groups. Nominally, parties are simply associations of voters for common ends. Actually, they are armies acting under commanding leaders who in many cases hold no offices. The evils of this "invisible government," as Elihu Root called it, were apparent. The political philosophy of Americans was based on the belief that mankind was steadily growing better. Hence a tendency to rely upon laws and political devices for correcting the ills of popular government. There was a glacier-like force of public opinion that could break down all opposition. What was most needed was the leadership of bold and far-seeing men.

#### POLITICAL AND SOCIAL PROBLEMS BEFORE 1917

*Finances and the Tariff (1908-13).*—Every growing unit in the country was harassed by questions of taxation and expenditure. The U.S. Govt. also was searching for new resources, and found them in the income-tax. This was made possible July 13 1909, by the submission of the 16th Amendment to the Constitution, which came into effect Feb. 25 1913. Another new resource of the Federal Govt. was a tax upon corporations levied on net income (Aug. 5 1909). The important question of reorganising the national banking system, so as to furnish a strong national institution, was debated from 1908 to 1912, and was the subject of an elaborate report by a National Monetary Commission; but no action was taken at that time. The net Federal debt was \$1,000,000,000, or only about \$11 per head of the population.

A financial resource over which Congress had sole authority was the tariff. Under strong pressure from members of the party to carry out the promises of the Republican Convention of 1908, President Taft, a few days after his inauguration, summoned Congress to meet in special session, for a "revision" of the tariff. As usual there was a long controversy, which resulted (Aug. 5 1909) in the Payne-Aldrich Tariff. The Act created a permanent court of customs appeals, with power to determine finally all questions as to the value of imports, together with a Tariff Board, expected to make investigations and recommend specific measures which Congress might adopt. As to rates, the Act was not very different from its predecessor, except for a decided increase of duties on cotton and silk manufactures. There was a loud outcry that the "revision" intended by the party platform was plainly a revision downward and not upward. Nevertheless President Taft signed the bill, and in a speech at Winona, Sept. 17 1909, surprised the country by declaring that it was the "best tariff bill that the Republican party has ever

passed." In the campaign of 1912 the tariff played very little part. It was recognised that a considerable revenue must be raised by import duties; and the large import trade showed that the existing tariff was not prohibitive.

*Political Reform 1908-13.*—When Roosevelt left the presidency in 1909 the position of President was at the highest point of authority that it had ever known. Most presidents have found their principal legislative influence in the veto; Roosevelt had followed the McKinley method of emphasising his wishes in personal discussion with members of Congress. He did more; he revived the Jacksonian method of announcing a legislative plan, and if Congressmen hung back, of appealing over their heads to the country at large. A similar policy was adopted by President Taft, who had many of the qualities of leadership. He was large, happy, genial, fond of his many friends; a cheerful, balanced man. He had served as first civil governor of the Philippines and as Secretary of War in the Cabinet of Roosevelt, who practically designated him as his successor. Nevertheless, as an avowed inheritor of Roosevelt's policies, he drew upon himself the opposition of Roosevelt's enemies while it soon became apparent that he was not relying upon Roosevelt's friends.

At this time "the primary" method of selecting candidates was spreading rapidly through the Union. Candidates for each party were selected by the ballots of the people, thus undermining the convention system. From nominations for local officers the new method had spread, by 1911, to state officers in numerous states; and after 1910 it began to be applied to the choice of delegates to the national party conventions. An unforeseen effect was that the official ballots were made upon the basis of party nominations, with an opportunity for independent voting. The primary thus became a part of the system of public elections, and therefore the party system was engrafted on public law, as a part of the Government.

The distrust of conventions and controlled elections extended to the numerous and powerful bosses in city and state Legislatures. Three new devices were set at work to curb them and to interest the electors in public measures. The first of these, the "referendum" (*q.v.*), was by 1909 spreading rapidly through the western states, as a means of checking legislative action contrary to public sentiment. The system, both in local and state government, can be traced from colonial times: most 19th-century state constitutions were submitted to a popular vote, and also many statutes if the Legislatures so directed. The referendum system furnished a mechanism, usually imbedded in state constitutions, by which on the demand of a sufficient number of voters, a statute could be held back from effect until submitted to a vote of the electors. What was to be done if the Legislature refused to enact a statute demanded by the people? The "initiative" was invoked, by which a designated number of voters could unite on a measure, which must then be submitted to the electors for their suffrages. Objection was made to all these methods as unconstitutional because they substituted direct action for representation. The referendum had been so long and widely used that it was hard to make out a case against it. The initiative was based on the general principle that the ultimate source of authority is not the Legislature or any public officer, but the people at large. In a test case (Feb. 1912) the Federal Supreme Court declined to rule that the initiative and referendum were contrary to a "republican form of government."

A third branch of this system of appeal to the people was the "recall" (*q.v.*), under which a public officer chosen by popular vote (and in a few cases those who were appointed in some other way) could be subjected to an election; and, should the majority decide against him, be thereby removed from office. In 1911-2 the question came up in connection with the proposed constitution of the new State of Arizona, which included a provision for the recall of judges. Because of this provision President Taft vetoed the Act of admission. The state withdrew the clause, was duly admitted in 1912, and thereupon proceeded to reinstate the recall. In practice, recalls proved to be few, and recalls of judges very few. A still wider application of the

principle of the responsibility of functionaries to the voters was the "recall of judicial decisions," which was advocated by Roosevelt in 1912, but proved to be more than the country desired.

United States Senators, till then chosen by State Legislatures, were next made subject to popular choice. Urged by public sentiment Congress submitted (June 12 1912) the 17th Amendment, which was duly ratified and added to the Constitution (May 31 1913). Under this, all elections to the Senate were to be made by direct popular vote. Another evidence of a rising feeling of responsibility in Congress was a statute (Aug. 7 1911) requiring candidates for the House and Senate to submit statements of the money raised and expended in their behalf and limiting the amount which they themselves might spend. One purpose of both these measures was to make it difficult for men to purchase their way into the Senate. On July 13 1912 Senator Lorimer of Illinois was practically expelled from the U.S. Senate for buying votes in the Legislature.

Another slow reform was in the ballot system. Most cities, towns and states were loaded down with long lists of the officers to be chosen. The result was an agitation for the reform commonly known as the "short ballot," by reducing the number of elective officers and increasing the officers to be appointed by the few elective officials. Working difficulties were found in many of these reforms. It was hard to keep the public keyed up to the necessary pitch of thought and attention at every election; but it was evident that the American people intended to free themselves from the shackles of "invisible government."

*Social Questions, 1908-12.*—The spirit of discontent extended to many questions outside of politics. Throughout the Taft administration there was an increasing pressure for "equal suffrage"—that is, woman suffrage—which, introduced in the territory of Wyoming in 1869, had gradually spread among the far-western states, and then begun working its way eastward. Again, both state and national governments were compelled to deal with the question of alcoholic beverages. From the earliest times there had been restriction on liquor selling and liquor sellers as well as punishment for the undue use of intoxicants. By 1909 in almost all states there was some form of general legal restriction—prohibition, local option, high licence or a state dispensary system. The question became national, because the liquor trade transported its wares from one state to another; and that brought it within the Interstate Commerce clause of the Constitution and the Interstate Commerce Act. Eventually by the original Package Act of 1890, Congress adopted the policy of prohibiting shipments of liquor into prohibition states. Pure food laws in force before 1909 were supplemented by the Drug Label Act (Aug. 23 1912), which greatly aided in preventing the adulteration of drugs.

Many questions arose out of immigration. The laws in 1909 forbade the entry of labourers under a contract to work in the United States, of convicts, diseased persons and the insane; but the execution of the laws was slack. The first statute looking toward decided control of immigration was that of Feb. 1907, which increased the grounds of exclusion, and at the same time provided a plan to help the immigrants in finding work. It also created an Immigration Commission, which in 1910 made a report in 41 volumes, strongly recommending the sifting of immigrants by testing their ability to read and write some language. Meanwhile, in the decade 1901-10 the number of immigrants rose to an average of a million a year. Since, however, the record showed that from 300,000 to 500,000 annually returned to their old homes, the actual rate of increase of population by immigration was no more than about  $\frac{1}{2}$ % annually.

*Labour Questions.*—Beginning with the common law principle that a combination of labourers to raise their wages was unlawful, the Legislatures and courts gradually changed their position and for many years acted on the counter principle that strikes were lawful. No legal obstacle was put in the way of the right to organise, first, by local trade unions, then by nation-wide unions for single trades, and finally by national unions combining many trades. To this was slowly added by the unions

the principle of the "right to labour," which means both that it is the duty of the community to see that the worker has a job, and also that at least the skilled workers have a kind of title in their employment, so that it is contrary to good morals for a "scab" to take the place of a striker.

The legal position of labour unions in these controversies was brought out by suits of national importance against unions. In the test case of *Gompers v. Buck's Stove and Range Co.* the charge was that the Federation, by posting the company in its publications as "unfair to labour," was boycotting, and thus infringing legal rights. Gompers, president of the American Federation of Labour, was convicted for contempt of Court on the ground that he had refused to obey a court order to abandon the boycott. In 1908 a suit was decided against a union of the hatters of Danbury (Conn.), who had attempted to boycott the products of a local hat manufacturer. The jury found a verdict of \$74,000 damages.

In the midst of these labour controversies there sprang up a new organisation, the Industrial Workers of the World (I.W.W.) which was an attempt on a large scale to organise the unskilled labourers, and to reach the goal of "one big union" for all trades. The movement was unwelcome to the unions of skilled labour. Strikes were frequent and often accompanied by acts of violence. Another phase of the labour situation was the spread of employers' liability laws through various states, and the passing of an Act of Congress (April 22 1908) for the protection of the employees of interstate railways. In June 1912 Congress added to its previous enactment of an eight-hour maximum regular day for public employees, by providing that all contract work for the Federal Govt. must also be on the eight-hour basis. As most labourers were voters they brought powerful influences to bear on state Legislatures and on Congress in favour of labour. On the other hand, the courts, particularly those of the states, were slow to recognise the changes in industrial conditions.

In addition, the courts began to use a system of labour injunctions: workman, labour unions and their members were ordered to abstain from committing acts which if committed would presumably violate a law and would therefore lead to a prosecution, in which the question of guilt or innocence could be settled by a jury. Instead, the courts by injunction would decide on the responsibility and affix a penalty not specifically laid down in any statute.

For years there was a Labour or Socialist Labour national party, which regularly nominated a candidate for the presidency and cast a small popular vote. It could not make progress because it was undercut by a standing Socialist party which cast from half a million to a million votes. Hence, in all the shifts of politics very few avowed Labour candidates were elected to state Legislatures or Congress. Furthermore, the members of the labour unions, about 5,000,000 all told, were not more than one-eighth of the men and women in the United States who worked with their hands.

*Trusts and Transportation 1887-1912.*—During the 20 years ending with 1910 it became clear that the most difficult question before the U.S. Govt. was the regulation of the vast aggregates of capital, commonly called trusts (*q.v.*), which, combined into corporations, aimed at the control of particular lines of business, and also of the railways. The efforts of Congress to adjust the question were registered in two lines of restrictive statutes, headed by the Interstate Commerce Act of 1887 and the Sherman Anti-Trust Act of 1890. Upon these was built a structure of decisions by the U.S. Supreme Court. To carry out and partly to avoid these decisions, the Mann-Elkins Act of June 18 1910 widely extended the Interstate Commerce Acts by including telephones, telegraphs, express and sleeping-car companies, and setting up a Commerce Court which was to render decisions on transportation questions. Federal control of railways on the whole worked well. The commission was a striking example of disregard of the principle of separation of powers, inasmuch as it was a rule-making body, an executive body, and a court which interpreted its own rules, subject as to some questions of appeal to the Federal courts.

The great problem of the trusts was much farther from a solution than that of the railways, because the large corporations were linked together through the holding and manipulation of stocks by capitalists and banks, and through the so-called "interlocking of interests." The only effective way of dealing with large corporations whose activities extended from state to state was to bring suit against them for monopolising or conspiring to monopolise in their lines of trade. It was considered a triumph when (May 9 1911) the U.S. Supreme Court rendered decisions against two of the most powerful trusts—the Standard Oil Company and the American Tobacco Company. The Court held that the anti-trust legislation must be interpreted by the "standard of reason"—namely, that a combination was not unlawful or against the public interest unless it actually caused a restraint of trade and commerce among the Federal states or with foreign nations. Having thus set up a "rule of reason" which Congress had refused to enact, and having created an example of judicial legislation, the Court proceeded in both the pending cases to hold that the companies were guilty of attempts to monopolise their lines of trade. As to penalties, the Court contented itself with ordering the offenders to disintegrate. Thenceforth the "rule of reason" required that positive proof must be adduced that a great combination was doing harm before it could be touched. The general danger of vast aggregations of capital was left out of account.

*Foreign Affairs.*—The fields of the diplomacy of the United States for the last hundred years have been American, Pacific, and in a much smaller degree European. In the Second Hague Conference of 1907 the U.S. delegates urged international arbitration; and in accordance with the general principles put forth at that conference, Elihu Root as Secretary of State secured 25 arbitration treaties with as many countries (1908). The United States and Great Britain arranged (Jan. 27 1909) to refer to the Hague tribunal their long-standing dispute on the Newfoundland fisheries. The result was a decision acceptable to both sides (Sept. 7 1910). President Taft, through Secretary Knox, secured in 1911 arbitration treaties with Great Britain and France; but the Senate insisted on inserting in these documents a reservation of all questions involving the "vital interest, the independence or honour of the nation," and in 1912 it refused to approve them. A long-standing difficulty with Russia, caused by the refusal of the Russian Govt. to recognise passports issued to Jews and some other people, was suddenly accentuated when (Dec. 18 1911) the commercial treaty of 1832 with Russia was abrogated.

In 1911 the Republican majority under President Taft's leadership initiated a policy of commercial reciprocity with Canada. An agreement was made with the Canadian Govt. by which each side should by legislation reduce or abolish duties on certain raw products and manufactures. With great difficulty the necessary bill was pushed through Congress (July 1911); but two months later the Canadian electors refused to support the reciprocity agreement, and the plan broke down.

*Latin America.*—Notwithstanding the position of the United States as the responsible holder of the Philippine Is., and hence an Asiatic power, the tradition of isolation continued to be a strong force in the public mind. Nevertheless no formidable public protest was made to a policy of special American intervention in Mexico, the Caribbean and the Isthmus region. The arrangements of 1902 made Cuba practically a dependency, subject in the last resort to decisions from the White House. President Taft continued the occupation of the Dominican Republic; consent of the Senate under a treaty to that effect having been obtained by Roosevelt in 1907. In 1911 Mr. Taft secured a convention by which Nicaragua gave exclusive canal privileges to the United States.

The Panama Canal was now approaching completion and the little Republic of Panama, which it bisected, though nominally an independent state, was in fact under American control. An Act of Congress was passed (Aug. 24 1912) for laying tolls on shipping, from which American ships engaged in coastwise trade were to be relieved. The British Govt. lodged a protest on

the ground that by its treaty with the United States the Canal was to be opened on equal terms to the ships of "all nations"; President Taft, however, stood by the Act, and the question was passed on to the next administration (see PANAMA CANAL).

Still more serious were the relations with Mexico, where, in 1910, a revolution headed by Madero, assailed the long established government of Porfirio Diaz and drove him after a few months out of the country. Mexico was thrown into confusion, and President Taft found it necessary to place troops on the border. In 1912 he proclaimed an embargo on the export of arms or military supplies to Mexico. Meanwhile the concessions and property of Americans in Mexico were threatened or destroyed. The Americans who had interests in Mexico began a steady pressure for intervention by the United States.

*Pacific Relations, 1908-12.*—Across the Pacific, clouds rose on the diplomatic horizon. The commercial treaties with Japan allowed a reciprocal freedom of residence and trade to the nationals of the two countries. The immigration of Japanese was very distasteful to the people of California, who undertook to restrict Japanese children to separate schools. Behind this difficulty was the rising power of the Japanese and their national spirit, greatly enhanced by their victory over the Russians in 1905. In 1908 Roosevelt sent round the world a powerful naval fleet, which visited Japan and was received with elaborate courtesy by a welcoming Japanese squadron exactly equal in number, ship for ship. In the Root-Takahira reciprocal note of Dec. 11 1908 (which was never submitted to the Senate), the United States practically admitted Japan's special interest in Asiatic affairs. The question of Japanese immigration was settled for the time being by a renewal of the commercial treaty (July 24 1911). It continued the previous "gentlemen's agreement," according to which, though claiming a right of immigration into the United States, the Japanese Govt. pledged itself not to issue passports to labourers.

*Politics 1909-12.*—In the action of Congress on many of the important issues above discussed no party lines were drawn, though such measures as the tariff and new taxes were distinctly Republican. On the tariff, some members from middle western states, particularly Minnesota, voted against the Payne-Aldrich measure of 1909. Another disturbance was due to resentment against the Speaker of the House, Joseph Cannon of Illinois, who exercised an authority that had been accumulating in the hands of Speakers for a hundred years. Through the union of various powers the Speaker virtually had a veto on any measure or proceeding which he did not like. Cannon kept too tight a hand; hence (March 19 1910) a group of Republican "insurgents" joined hands with the Democrats to reduce his prerogatives till the Speaker of the House became simply a partisan moderator.

A new issue upon which both parties were divided was covered by the general term "conservation." Although most of the arable land had passed out of its possession, the Federal Govt. was still the possessor of great tracts of forest, of mineral lands and of water power. Congress in 1902 provided for a system of irrigation, the cost to be advanced by the Govt. and repaid in instalments by the users of the water. President Roosevelt became interested in stopping the waste of timber and minerals, in preserving part of the gifts of nature for future generations, and in retaining public ownership of the utilities of the country, particularly the forests and streams. In 1910 new statutes provided for a fresh classification of land and for the reservation of coal by the Government.

*Roosevelt and Wilson.*—By 1910 it became clear that the Republican party was weakening, and that President Taft's popularity and influence were lessening. The state and congressional elections of 1910 were unfavourable to the Republicans. The insurgents, who soon came to be called Progressives, gained most of the Republican districts in the west, and the Democrats gained about 50 seats in Congress. This result transferred to the Democrats the control of the House, while in the Senate they secured 41 of the 92 members.

A group of dissatisfied Republicans gathered about Senator La Follette of Wisconsin as a leader and presumptive candidate

for President. Meanwhile state Legislatures were passing primary laws which included the election of delegates to national nominating conventions. This made it easier to break through the old line organisations, as La Follette had done in his own state. Taft's friends and supporters naturally expected that the President would be renominated.

All these calculations were disturbed by the greatest personality in the country, Theodore Roosevelt. A few weeks after leaving the White House (1909) he started on an expedition to Central Africa, and was thereafter received in Europe as the ex-President of the most important of republics and as a commanding personage. He returned to the United States (June 18 1910) to find political conditions little to his liking. Most of his friends had disappeared from the Administration; his policies seemed to him to have been slighted. Taft did not satisfy the ex-President, and the two drifted apart. On Aug. 31 1910, at Osawatimie, Kan., Roosevelt set forth a programme which he called "the New Nationalism," favouring publicity of the accounts and proceedings of trusts, a tariff commission, a graduated income-tax, an adequate army and navy, conservation, protection of labour, and the direct primary with the recall of elective officers. For the time being Roosevelt made no direct movement toward standing for the presidency. Meanwhile several of the western states, particularly California under the guidance of Governor Hiram Johnson, accepted a radical programme of political and social reform. A formal breach with Taft and the open candidature of Roosevelt seemed inevitable. The crisis came when (Feb. 12 1912) President Taft in a speech alluded to the Progressives (evidently having Roosevelt in mind) as "Extremists—not Progressives; they are political emotionaries, or neurotics." This was taken as a challenge, and a few days later Roosevelt openly declared himself a candidate, adding, "My hat is in the ring." In a large group of states delegates favouring Roosevelt were elected.

*The Election of 1912.*—As the convention held in Chicago approached, the lines of battle were developed. Behind Taft were Barnes of New York, Penrose of Pennsylvania, Crane of Massachusetts, and other "stand-pat" leaders. Among those in favour of Roosevelt were James Garfield of Ohio, Pinchot of Pennsylvania and a strong body of Republican governors. Roosevelt himself went to Chicago, established headquarters, and threw his immense energy and enthusiasm into the campaign. The convention was a scene of unusual excitement. Out of the 1,076 delegates nearly 400 were pledged to support Theodore Roosevelt.

The critical decision was made in the preliminary meetings of the national committee, which was strongly "stand-pat"; for that committee had to decide upon the right of claimants to be inscribed in the preliminary roll of delegates. In the end, every contest except one was settled in favour of the Taft claimants. The shifting of 30 delegates from one side to the other would have brought about a "stampede" to Roosevelt, but they were not to be had. Roosevelt advised his delegates to take no further part in the proceedings. At the final roll-call, June 22, there were 561 votes for Taft, 58 scattering and 107 for Roosevelt, besides 344 Roosevelt men not voting. In the last issue, therefore, Taft had a majority of 50 votes out of 1,070. In the minds of the conservative Republicans Roosevelt was extinct. In the minds of Roosevelt and most of his followers the nomination was a violation of the principles of popular government. Roosevelt openly advised a bolt. This was duly accomplished by a formal Progressive Convention. It met in Chicago in Aug. and nominated Roosevelt for president and Hiram Johnson for vice-president.

Meanwhile the Democratic Convention at Baltimore met under the guidance of William J. Bryan, who was in a position to dictate the choice. The apparently sure candidate was Champ Clark of Missouri, Speaker of the House of Representatives. But under the rules of the Democratic Convention requiring a two-thirds majority, he was finally defeated by Woodrow Wilson, Governor of New Jersey. The platforms of the two old parties were of the usual type. The Republicans declared for protective

duties. The Democrats stood by their platform of a tariff for revenue only, additional regulation of the railways and presidential preference primaries. The Progressive platform was a general programme of political reform and "an enlarged measure of social and industrial justice."

*Woodrow Wilson's Victory.*—Not platforms, however, but men, appealed to the voters. All three candidates took the field. From the first it was clear that the real fight was between Roosevelt and Wilson. The Progressives were well organised, and their convention and campaign included many women. The final question was whether Roosevelt could draw to himself a sufficient number of Democrats to reduce the Democratic vote below the winning point. The result in Nov. showed that the Democrats in the main stood by their regular party candidates. The total popular Democratic vote, 6,286,214, was only about 120,000 less than in 1908. The total Taft and Roosevelt vote combined was almost exactly the same as that of the Republicans in 1900. Roosevelt polled 4,126,020 popular votes to 3,483,922 for Taft; but he carried only six states, with 88 electoral votes, against 2 states with 8 votes for Taft, and 40 states with 435 votes for Wilson. The centre and soul of the Progressive movement was Theodore Roosevelt. He had an ardent habit of mind; he felt intensely; he spoke with tremendous energy and conviction; he was accused by his critics of "inventing the Ten Commandments." He was not only the head of a party, he was the head of a political cult (see ROOSEVELT, THEODORE).

*Woodrow Wilson.*—In that respect he was closely paralleled by Woodrow Wilson, who, on March 4 1913, was inaugurated as President. Born in Staunton, Va., in 1856, of Scotch Presbyterian ancestry, he graduated from Princeton in 1879, essayed the practice of law, then was a professor in several colleges. From 1902 to 1910, he was president of Princeton University. He was an easy and attractive speaker, and had a remarkable literary style. (See WILSON, WOODROW.) As Governor of New Jersey during 1911 and 1912 Gov. Wilson had opportunity to show his skill as a party leader and his interest in reform. In 1912 Woodrow Wilson was taken up by Bryan, who saw in him an exponent of the political principles for which Bryan had stood and a President who could meet the Progressives on their own ground. On the eve of his inauguration *The New Freedom* was published, a book based on salient passages from his campaign speeches. It was in effect a confession of political faith, a forecast of what the President intended. He protests against political conditions and methods, and points out the baleful influence of corporations and trusts.

In making up his Cabinet it was only reasonable that Bryan should enter it. He was made Secretary of State, an office for which he had little adaptation. To a new Cabinet office recently created by Congress, the secretaryship of the Department of Labor, Wilson appointed W. B. Wilson, a strict labour organisation man. Lindley M. Garrison, Secretary of War, and Franklin K. Lane, Secretary of the Interior, were strong men. Albert S. Burleson, Postmaster-General, and Josephus Daniels, Secretary of the Navy, had insufficient training for their duties. David F. Houston, of Missouri, was made Secretary of Agriculture, William G. McAdoo, Secretary of the Treasury, and James C. McReynolds, Attorney-General. Most of the members of the Cabinet were men who could be trusted to follow the President's lead. One remarkable statesman not included in this list was Col. E. M. House of Texas, who for six years was the President's most trusted counsellor and political friend without holding any political office. In the minor civil service Wilson carried out his principles by enlarging the classified list of posts which could be entered only by competitive examinations.

A genial man, who could be a delightful companion, full of experience and of Scotch Presbyterian humour, President Wilson had a powerful mind, an amazing skill of expression and an intense belief in the power of ideals to arouse and inspire a people. He thought he had no need of conferences, of feeling the public pulse, of mixing with members of Congress and party leaders, of personally greeting the average voter.

*Finance and Tariff 1913.*—The election of 1912 carried with it a safe Democratic majority in the Senate and a two-to-one majority in the House. On April 8 1913 the President created a surprise by appearing in person to address the two Houses of Congress jointly at the opening of a special session, instead of sending a written message. This practice he followed throughout his administration, with great effect. He felt himself not only chief magistrate of the nation, but head of the Democratic party, and practically the premier of the Government from whom ought to proceed plans for important legislation.

A special session was called particularly to frame a tariff Act. Representative Underwood, chairman of the Committee of Ways and Means, gave to the new measure his name and experience. The purpose of the statute was to enlarge the free list of raw materials, foodstuffs and some manufactures, to make a moderate reduction of the protective duties, and to correct some of the things which made the Payne-Aldrich Act unpopular. Included in the statute was an income-tax, at last made possible by the adoption of the 16th Amendment (Feb. 25 1913), which was expected to supply any revenue which might be lost by the reduction of duties (*see INCOME TAX: United States*). A Tariff Commission was created to make researches into the workings of the Act and to find out what was the actual difference between the cost of labour in the United States and in foreign countries (Oct. 3 1913).

The powerful influence of the President was again exerted to secure a systematic banking system, with the result that (Dec. 23 1913) the Owen-Glass Federal Reserve Bank Act was added to the statutes (*see BANKING*). The principle was to create a national institution, which was to be divided into 12 regional banks, in each of which was a body of directors, besides the central organisation in Washington. In these 12 subdivisions clustered such banks, whether national or state-chartered, as chose to accept. The new institution was also to issue a new form of paper money. The system from the start was recognised as a large national asset. At the same time a Rural Credits Act was passed (July 17 1916), which created a special group of banks to lend money to farmers on the security of their farms. Both banking systems worked smoothly and efficiently.

*Transportation, 1914-6.*—Under a statute of March 1 1913 the Interstate Commerce Commission was authorised to enter on an elaborate valuation of the railway property throughout the country as the basis of a judgment as to what was a reasonable profit. The Supreme Court supported recent legislation by compelling the pipe-lines to accept the status of common carriers, and by breaking up some of the railway combinations, particularly that of the New York, New Haven and Hartford. Down to the middle of 1916 the railways were doing well on the prevailing low rates for passengers and freight. The Panama Canal was now approaching completion. This was the first great agency of transportation owned and managed by the U.S. Government. President Wilson used to the utmost his personal influence for a bill to repeal discrimination in favour of American-owned vessels, of which the British Govt. had complained; it became an Act, June 15 1914. On Aug. 15 the first steamer passed through the Canal from sea to sea and in a few months the Canal was paying its own way. A new question of transportation was arising through the rapid development of motor vehicles. At first a plaything, then a luxury, by 1908 they were spreading throughout the land. The attention of the whole country was called to the absolute necessity of good roads. In 1916 Congress passed an Act appropriating approximately \$85,000,000 to be paid in about five years to such states as would contribute equal sums for good roads.

*The Trusts, 1914.*—A few hours before the end of President Taft's term a congressional committee reported against the "great and rapidly growing concentration of the money control and credit in the hands of a few men." In June 1914, in a suit involving the International Harvester Co., the U.S. Supreme Court upheld state anti-trust laws. The ring of law and justice seemed to be drawing closer round the great offenders. Yet these offenders still flourished; and huge corporations, such as the

U.S. Steel Corp., paid dividends on thousands of millions in stock and bonds. President Wilson urged successfully a radical amendment of the Sherman Act (Oct. 15 1914) against discriminating freight agreements, interlocking directorates, and holding corporations.

Another branch of the same attack on the money power was the Federal Trade Commission, created Sept. 26 1914, which was an attempt to find means of dealing with corporations engaged in interstate commerce other than banks and common carriers. In the same direction went the "blue sky laws" passed in this period by many states, to break up the practice of floating the stock of companies which had no property more substantial than the atmosphere.

*Labour, 1913-7.*—The example of capital, in rolling itself into masses too great to be controlled by ordinary means, was followed by labour. The American Federation of Labour was a loosely woven council of representatives from the great trade organisations. It did not undertake to call strikes, though it was likely to support them, and it had great effect in bringing about combined and simultaneous demands for the various items in the labour programme. The leaders fixed upon an eight-hour day as the basic working time. The next item was the minimum wage, which made its way slowly and was not altogether acceptable to labour. Another demand was that American citizens should have preference over aliens in employment. Labour in general was unfriendly to child labour and was, therefore, interested in a Federal statute of Sept. 1 1916, to prevent the transport of products made by child labour under specified conditions.

As the labour unions gained in numbers and strength they used their energies in favour of the "closed shop," a system by which union men refused to work in any establishment where men not members of the union were also employed. From this idea rapidly developed the system of sympathetic strikes, in which members of one union back up another union by refusing to handle or use or transport products of nonunion labour. Hence boycotts, and perhaps ruin for employers who had no difficulty or quarrel with their own workmen. Never in the history of the United States had there been so many and so violent strikes as from 1913 to 1917. The I.W.W. organised long and tumultuous strikes among the silk weavers of Paterson, N.J., and the textile workers of Lawrence, Mass. In the trying years of 1916-7, violent strikes were directed not only against non-striking workmen, but against the public peace. In July 1917, at Bisbee, Ariz., the tables were turned. A kind of vigilance committee seized and carried out of town, with orders not to return, about 1,200 striking miners and their friends. No jury would convict those responsible for this illegal action. The most serious of all these labour struggles was the threatened strike in 1916 of the large and very powerful unions of railway employees. President Wilson intervened and all but compelled Congress to pass (Sept. 3 1916) the Adamson Act by which a basic eight-hour day was secured with *pro rata* for overtime. The Supreme Court upheld this statute, which went to the furthest verge of the Federal Government's authority over labour matters.

*Social Movements, 1913-7.*—These struggles between the railways and the courts, between the trusts and Congress, between labour and state governments, between strikers and the President of the United States, are part of American history because they were vital to the welfare of the country. Neither the capitalist nor the labourer respected the restraint of state legislation. It was apparent that in the long run the country would go back to the "might makes right" of the middle ages, unless some peaceful settlement could be made by a force that must be respected. The farmers everywhere were aroused, for they looked on railways as hostile to their interests, by overcharging for carrying their products; and they resented the trusts, which they believed raised prices. The anti-liquor forces steadily developed strength. They urged out-and-out prohibition and secured it in more than half the states. At the end of 1917 war prohibition was enacted by the Federal Govt. and also prohibition in the District of Columbia. On Dec. 19 1917 a two-

thirds majority was secured in Congress for a prohibition constitutional amendment—the 18th Amendment—which was at once submitted to the states. Woman suffrage also advanced steadily. Congress submitted a woman suffrage amendment in 1919. Thus changes that had been 50 years on the way finally were brought about by the force of public opinion. A change was also visible in the attitude of the country toward immigration which Congress was determined to reduce by an intelligence qualification. A new bill (Feb. 5 1917) was passed over Wilson's veto. Besides a literacy test it raised the head-tax to \$3 and excluded oriental labourers coming from certain geographical areas, which did not include Japan but did apply to Hindus and Malays.

*Educational Progress, 1909-21.*—The decade following 1909 was marked by a new sense of the possibility of general education, and the need for a more direct, searching and practical type of education. The country was accustomed to a system of graded public schools, offering the "common school education," and leading up to a few endowed and private schools, and to thousands of public high schools, which were expected to prepare the small proportion of young men who went on to institutions of higher education. By 1910 girls were given about an equal chance in the public elementary and secondary schools, and in a large number of coeducational colleges and universities, besides a small group of high-class colleges open to women only. Secondary education was subdivided into literary, commercial and industrial schools. The institutions of higher learning set up new professional departments, including the intensive study of education and separate schools of science, engineering, agriculture and other specialities. Private enterprise created a great number of so-called business colleges, and a few very efficient trade schools.

Nevertheless there was general complaint that the schools did not relate themselves to the life of the community. A National Society for the Promotion of Industrial Education became the focus of a movement to organise what now became generally known throughout the country as vocational education. A national commission was appointed by President Wilson, in 1914, to consider the whole subject. The resulting Smith-Hughes Act (Feb. 22 1917) created a Federal Board for Vocational Education which framed an elaborate plan for instruction in the four vocational fields of agriculture, commerce, industry and home-making. The Act promised to appropriate Federal funds rising to about \$7,000,000 in 1925 and thereafter, to be paid to such states as would match these funds dollar for dollar.

Private enterprise accompanied this movement by building up advanced engineering and trade schools of a high type, such as the Carnegie Institute at Pittsburgh; by improving the private commercial schools and by establishing advanced schools of business training in colleges. Some of the great manufacturers, especially in the automobile trade, set up schools within their own works.

When the United States plunged into the World War in 1917, Government established a variety of vocational schools to train the men for the numerous specialities of military service. It made use of the shops and other vocational facilities of the existing schools and colleges. Great sums were raised by special "drives" among the alumni and friends of the endowed institutions, and the state universities were allotted hitherto unheard-of grants. The strictly vocational schools were admitted into fellowship with the other institutions. (See EDUCATION: United States.)

*Wilson's Foreign Policy.*—Woodrow Wilson was naturally a man of peace, and so emphatically was Secretary Bryan. They set themselves to aid the cause of general peace by arbitration treaties. Secretary Bryan prepared a definite project for treaties by which the nations concerned should, in case of difficulties, pledge themselves to submit their grievances and claims to a special examining commission and to abstain from war or preparations for war until the commission should have had time to report. The presumption was that a sensible nation would submit to the judgment of an impartial tribunal. There was little difficulty in concluding more than 30 treaties upon this

basis in the course of a year, but none was put into effect. The truth is that the American people as a whole were little accustomed to international questions and had no definite foreign policy.

*Philippines and Caribbeans.*—The Govt. of the Philippine Is. was altered by setting up the first Filipino Assembly in 1908. In response to the pleading of President Taft, Congress in 1909 grudgingly included them within the customs boundary of the United States. Under President Wilson, Gov.-Gen. Cameron Forbes was withdrawn and Burton Harrison was appointed his successor, to carry out a policy of liberalisation and preparation for independence. The Filipinos were allowed to hold a majority of the seats in the Commission, which became a kind of administrative Upper House. Filipinos were substituted for Americans in many of the civil offices. The people were thus given a definite opportunity to govern themselves. The Jones bill, enacted Aug. 29 1916, greatly enlarged the power of the popular part of the Government, and the Commission ceased to exist. The Act promised that the Filipinos should be given their independence when their ability to govern themselves should be demonstrated.

At the other end of the American sphere of influence, Cuba, while nominally independent, remained a protectorate of the United States. On March 2 1917, the Porto Ricans were for the first time made American citizens and received a popular government of two elected Houses. President Wilson continued the administration of the Dominican Republic which dated back to Roosevelt. He also took military control of Haiti in 1914, and followed it by a controlling treaty which was ratified by the Senate (Feb. 28 1916). He carried even farther Taft's policy in Nicaragua by a treaty (ratified Aug. 14 1914) which converted that country into a virtual protectorate. Another area came under control of the United States by a treaty for the annexation of the Danish West Indies proclaimed in 1917. These islands were duly organised under the title Virgin Is. of the United States. Little opposition was made to this creation of a virtual empire, including dependent provinces.

*Latin America and the Orient, 1913-7.*—The peaceful policy of the United States towards its neighbours was severely tested by disturbances in Mexico. In 1913 Madero, president of that turbulent republic, was murdered, presumably by order of Huerta, an insurgent officer, who thereupon declared himself the head of the state. The almost invariable policy of the United States had been to recognise any *de facto* head of a Latin-American Govt. without inquiring into the source of his title. But on this occasion President Wilson adopted what he called a policy of "watchful waiting." He steadily refused to recognise Huerta, against rival revolutionists. In April 1914 a trifling dispute arose at Tampico as to a salute of the American flag, and Wilson, apparently yielding to strong public sentiment, ordered the navy to attack and capture Vera Cruz, of which the United States remained in possession for some months. The real object was to discredit Huerta, who was compelled to flee the country. When in 1915 the brigand Villa raided the town of Columbus, N.M., the President ordered a military expedition under General Pershing to advance into the interior of Mexico. It remained about eight months, without capturing Villa or accomplishing any other definite result. The three friendly nations of South America—Argentina, Brazil and Chile, commonly known as the "A B C Powers"—offered a kind of mediation. At their suggestion Carranza was recognised as president by the United States. Disorder continued, and in May 1920 Carranza was overthrown and killed by the troops of Obregon. For a time thereafter Mexico emerged from the state of revolution.

This long controversy was highly disturbing to the desired close relations with Latin America in general. In spite of five Pan-American congresses and several scientific congresses, in spite of visits of Roosevelt and of Root and Knox as Secretaries of State to South America, there could be no harmony if the United States were to continue "administering" small and defenceless Latin American nations and waging undeclared wars with Mexico. Nevertheless, President Wilson in a speech at Mobile (Oct. 27 1913) declared that the United States had no

designs on the territory or independence of its Latin-American neighbours. Colombia, too, had a grievance arising out of the loss of the isthmus when the Panama Canal Zone was annexed in 1904. The succeeding Republican Administration in 1921 secured a treaty to pay to Colombia \$25,000,000 as a kind of reparation.

In regard to the Far East, Wilson had little opportunity to develop a policy. He began by disavowing the plans made under the advice of President Taft for a loan by American bankers to China. He argued with the people of California because they insisted on passing a statute restricting alien ownership of lands by Japanese residents. The World War soon made the United States and Japan temporary allies, and on Nov. 2 1917 the Lansing-Ishii note, on the same plan as the Root-Takahira note of 1908, set forth that the United States recognised Japan's "special interests in China." (See JAPAN).

*Neutrality.*—The United States in 1914 expected to remain indefinitely at peace, as was shown by lack of anything that could be considered national military preparation in the terms of modern warfare. When on Aug. 4 1914 President Wilson issued a proclamation of neutrality as between the two groups of European nations just engaging in a gigantic struggle, the authorised military establishment was about 107,000 men, of whom some 87,000 were enrolled. The United States had not one military aeroplane of approved type; had only four modern heavy field guns and no transport for them; had not a trench bomb or a mine-thruster; nor considerable supplies of any weapons or equipment except 800,000 excellent rifles; nor any officers experienced in the kind of warfare used in recent wars; nor any instruction camps for officers or men. The navy included a fleet of battleships recently built, but weak in small and swift vessels and particularly in submarines. The militia proved to be of little service, though Secretary Bryan publicly declared that the nation needed no preparation, for it "could raise a million men between sunrise and sunset."

Neither the foreign policy nor the diplomatic organisation of the United States was fitted for such a crisis. The traditional Monroe Doctrine was expected to keep the nation out of dangerous controversies with the other American states. The counterpart principle of isolation forbade the United States to take any part in European crises or wars. As a neutral it stood by the principle of "freedom of the seas," by which was meant in particular the right to carry on commerce with all belligerents in case of war, subject to the limitations of the then acknowledged international law as to contraband and blockade. At the beginning of the War thousands of American tourists and residents were caught in the mobilisation of the great European armies, and the Government aided in bringing them home. A few weeks later relief was organised on a large scale for the Belgian people, most of whose country was overrun and held by the Germans. This system soon included French refugees, the unhappy peoples of Serbia and Asia Minor and other combatant or non-combatant sufferers, besides the sick and wounded of the contending armies.

*Difficulties with the Belligerents, 1914-7.*—The United States was compelled at once to take into account the relation between the war and American industries, commerce and finance. Heavy loans were placed in the United States by Great Britain, France and Russia. As fast as the money was borrowed it was spent in the United States for the purchase of food, clothing, animals and especially munitions. President Wilson issued a proclamation (Aug. 18 1914) advising that the people remain neutral "not only in act but in word and in thought." Such neutrality was impossible. In the first weeks of the War German commerce was driven from the seas. The command of the sea by the Allies very nearly cut off trade of any kind between the United States and Germany and Austria, while commerce continued in ever-increasing volume with England and France. This disparity led to protests on the part of the German Govt., and also to lawless acts perpetrated or directed by agents dispatched by the German Govt. for the purpose of paralysing the munition factories. Violent antipathies were caused by the German methods of carrying on war, and particularly the treatment of

the occupied areas of Belgium and France. The American population included hundreds of thousands of citizens of the belligerent countries, many of whom attempted to return to their homes in order to serve in the army. The road for such recruits was blocked for the Germans and their allies, but open to the Allies. For the first time in half a century the United States found within its own borders the sharpest division on questions of foreign policy.

On the other hand, the war trade brought immense profits. The favourable balance of trade rose from \$690,000,000 in 1913 to \$1,770,000,000 in 1915 and \$3,000,000,000 in 1916. This prodigious debit was balanced by about \$3,000,000,000 sent to the United States in securities and gold, besides \$2,000,000,000 in foreign War bonds. Under these circumstances genuine neutrality was out of the question. A decided preponderance of sympathy developed toward the western Allies, who were profitable customers, were in close and almost undisturbed intercourse with the United States and were considered to be fighting against a ruthless, arrogant and dangerous autocracy.

*International Controversies, 1914-7.*—The internal tension of the United States was tightened by the insistence of Germany on the right to use new weapons, tactics and practices of war, without the traditional limitations of international law, without mercy to non-combatants, on the basis of "a law of necessity." No able-bodied German man or woman was really a non-combatant; the Germans insisted that they must regard all civilian enemies as combatants. There was no way to stop them without using similar new methods of warfare.

Great Britain, which in the London Maritime Conference of 1912 had shown some disposition to enlarge the privileges of neutral commerce, now seized American ships and shipments, and arbitrarily extended the list of contraband, until (Dec. 26 1914) a dispatch signed by Secretary Bryan, but expressing the conclusions of President Wilson, made a protest. In the course of 1915 the British Govt. began to apply the American principle of "continuous voyage" as applied by the United States during the Civil War to cover shipments to neutral ports in cases where those shipments were likely ultimately to reach Germany; and also where they might replace products of the neutral countries that could thus be spared for Germany; or if the neutral countries declined to make a hard and fast agreement not to reship.

In 1916 the British were practically blockading neutral European ports and capturing vessels, American and other, wherever they liked.<sup>1</sup> The Central Powers set up a new war practice of using submarines as commerce destroyers. The American Govt. protested. A crisis came through the sinking by a submarine of the British passenger liner "Lusitania" (May 7 1915), with the loss of 113 American lives. That sinking was a deliberate act of the Germans to test the temper of the United States. Apparently they were greatly surprised when the people of the United States rose in resentment. President Wilson, who had earlier insisted on "strict accountability," insisted on a sharp protest. Mr. Bryan thought milder measures sufficient, and on that issue resigned the Secretaryship of State (June 8 1915), being succeeded by Robert M. Lansing. The correspondence went on for months until (May 4 1916) Germany at last informed the American Govt. that merchant ships would not be sunk without warning and an opportunity to save non-combatant lives. Meanwhile, throughout 1915 and 1916, systematic violations of the neutrality laws of the United States by Germans and Austrians caused the dismissal of the Austrian ambassador to the United States and of the two most obnoxious members of the German ambassador's staff. It was the belief that they would hesitate at nothing during the War.

*"Preparedness."*—By the end of 1915 it became clear that with or without their own desire, the people of the United States might find themselves involved. President Wilson desired peace. A day or two after the sinking of the "Lusitania" he spoke of there being such a thing as "a nation that was too proud to fight." In his message of Dec. 1915 he urged national defence and the protection of American shipping. Long before

<sup>1</sup>For a discussion of the legal principles involved see BLOCKADE.

this time the War had brought about a violent change in the economic conditions of the country. The great demand for food-stuffs raised the price of grain and other farm products. The high cost of living became a political issue. The munition factories offered unheard-of wages and drew hundreds of thousands into improvised towns. The War caused a great change in immigration. Hundreds of thousands of men left the United States for Europe, while the net immigration fell from 1,200,000 in 1914 to 300,000 in 1916.

*The Election of 1916.*—In the midst of this turmoil and confusion of business came the preliminaries of the presidential election of 1916. President Wilson carefully abstained from taking sides between the Allies and the Central Powers; but the aggressive submarine policy of Germany provoked a much sharper tone than did the aggressions by the English. He felt the need of caution, particularly because a growing group of men inside and outside Congress, among them Roosevelt, were coming to the conclusion that eventually the United States would have to join in the War.

The Republican nominating Convention met in Chicago, June 7. A strong effort was made by friends of Roosevelt to capture the Republican Convention, but the "stand-pat" Republicans had control of the party machinery. The Progressives—who in Nov. 1914 had cast 1,800,000 votes for congressional and state candidates—also met in convention in Chicago. Their purpose was to compel the Republicans to nominate Roosevelt as the only means of healing the breach. That effort failed: the Republicans nominated Justice Hughes of the Supreme Court, who had been a reform governor of New York State. The days of the Progressive party were numbered.

In the Democratic Convention (June 14) there was practically no opposition to Wilson and his running-mate T. R. Marshall. The platform in many respects was similar to that of the Republicans. Both favoured woman suffrage, the conservation of national resources and national enforcement of child-labour laws; both reaffirmed the Monroe Doctrine. But the Democrats upheld tariff for revenue only; they endorsed the promise of ultimate independence to the Filipinos; they commended the establishment of a Federal Trade Commission; and they approved a merchant marine owned and operated by the Federal Government. In the campaign Roosevelt publicly supported Hughes, though it was well known that he felt no enthusiasm for him. The only "slogan" that caught the public ear was favourable to Wilson: "He kept us out of war." On election day Wilson received about 9,000,000 popular votes against 8,500,000 for Hughes, and was chosen by a very close vote in the electoral college.

#### THE WAR AND THE PEACE

President Wilson stood in a very strong position in the United States and in the world. He had been re-elected. His policy was approved. He felt that he had the nation politically united. He soon began to take a firmer tone against the Allied system of neutral blockade. Wilson hoped that the one great neutral nation might bring about peace. On Dec. 18 1916 he sent an appeal to the warring Powers to come to an understanding of each other's demands. On Jan. 22 1917 in an address to the Senate on foreign affairs the President described the replies he had received to the identic note of Dec. 18.

The Central Powers united in a reply which stated merely that they were ready to meet their antagonists in conference to discuss terms of peace. The Entente Powers have replied much more definitely, and have stated, in general terms indeed, but with sufficient definiteness to imply details, the arrangements, guarantees and acts of reparation which they deem to be indispensable conditions of a satisfactory settlement.

He went on to speak of an "organised common peace," and of a "peace without victory"; he outlined the principle of self-determination, declaring that "Governments derive all their just powers from the consent of the governed," and that "no right anywhere exists to hand people about from potentate to potentate as if they were property." The practical German answer was a brief note communicated by Ambassador Bernstorff

to Secretary Lansing (Jan. 31 1917), withdrawing the conditional pledge given in May 1916 and announcing that the Germans would shortly resume unrestricted submarine warfare. High military authority in Germany was convinced that the Americans would never sacrifice the large profits of export trade and incur the huge expenses of war merely for the sake of a question of neutral maritime rights.

Immediate steps were taken to make the American Navy ready for war. For a time the President dallied with a plan of arming merchant ships. One result of the controversy was the adoption by the Senate (March 8) of a mild and cumbersome method of cutting short debate by closure. During Feb. and March 1917 a few American vessels were torpedoed by German submarines. On Feb. 8 the Government published an intercepted German despatch to the Mexican Govt. asking it to join in the War, promising it the "former Mexican provinces," long incorporated in the United States. The participation of the United States in the War was now inevitable. A formal declaration of a state of war was signed by the President (April 6) after a House vote of 373 to 50 and a Senate vote of 82 to 6, which stated that war had already been begun by Germany. Relations with Austria and Turkey were at once broken off, but the declaration of war with Austria was delayed until Dec. 7 and no declaration was ever made against Turkey or Bulgaria.

The breach with Germany was a spontaneous national action representing a national belief that the United States could no longer live in peace with such a nation as Germany had become. As President Wilson put it the War was to make the world "safe for democracy."<sup>1</sup> Moreover, there was widespread sympathy with the three western Powers closest to the United States in their political principles and system of government. Wrath was aroused by the German treatment of the people of Belgium and other conquered countries. In some minds there existed a genuine and well grounded fear of a future attack upon the United States by Germany if the resistance of the Allies should be destroyed. Amid all the motives for the War, the one thing was that the American people recognised Germany as an enemy, and the enemies of Germany as natural friends and partners in the great enterprise of subduing "the Hun."

*War Measures.*—Passionate national spirit, patriotism and urgent reasons for war were all useless unless the United States could enrol, train, equip, convey and continuously supply an immense army. The American Navy, though the vessels were good and the crews skilled and well commanded, was in no position to give direct aid in the process of destroying the German Army. What was most needed was to raise and convey to the fighting front a large force of American troops.

Soon after the declaration of war by the United States, missions from the various Allied countries were sent to America. The British Mission, headed by Arthur (now Lord) Balfour, British Foreign Secretary, reached Halifax April 20 and proceeded to Washington. The French Mission, headed by René Viviani, the former Premier, and including Marshal Joffre, landed April 24. Other missions came from Italy, Belgium, Russia, Rumania and Japan. The United States was able at once to help the western Allies in their pressing financial difficulties. Taxes were low and little felt; money abounded. Under Acts of Congress beginning Oct. 17 1917, the Allies received essential credits, which amounted eventually to \$9,500,000,000.

These enormous payments were made possible by the Liberty Loans. In June 1917 4,000,000 people joined in offering \$3,000,000,000 to the Government; and at the end of the War the interest-bearing debt had increased from \$972,469,290 on Dec. 31 1916 to \$25,234,496,000 in 1919. These loans were supplemented by the War Revenue Act (Oct. 17 1917) and later statutes, which laid a variety of new taxes, increased the income-tax heavily, and combined with it an excess-profits tax to bring

<sup>1</sup> "To fight thus for the ultimate peace of the world and for the liberation of its peoples, the German peoples included; for the rights of nations great and small and the privilege of men everywhere to choose their way of life and of obedience. The world must be made safe for democracy." (Message to Congress April 2.)

into the Treasury unreasonable profits likely to be made in the war industries.

All traditional limitations on raising an army were discarded. Ex-President Roosevelt asked permission to recruit a division for a special volunteer force, but the President refused him a commission. On May 18 the Selective Service Act was passed which provided for the enlistment of a million men by "selective draft." When called up, the men had to be clothed, housed, fed and drilled. Thousands of officers were necessary, and training camps, both for men and officers, were established on a vast scale. In May 1917 a few American destroyers reached England. On June 9 Gen. J. J. Pershing, who had been selected as commander-in-chief, arrived in England. On June 26 a small detachment of U.S. troops reached Europe. New branches of military service were established, among them the Chemical Warfare Service which provided materials for lethal gases and for gas-masks and other means of resisting the enemy attacks. Congress, on July 24, appropriated \$640,000,000 for aviation. By Aug. about 700,000 men were enrolled in the army and 230,000 in the navy.

*Control of Industry and Transportation.*—The establishment of huge war industries put a great strain on the industry and transportation of the United States. On Aug. 10 1917 a Food Control Act gave the President powers never before conferred with regard to food and fuel (see FOOD SUPPLY). Herbert C. Hoover, of California, who had distinguished himself in the management of the Red Cross in Europe, was made Food Administrator with large powers. Before the War ended he had established "meatless" and "wheatless" days; the price of grain was fixed; eventually the farmers were assured \$2.20 a bushel for their wheat crops. H. A. Garfield, Fuel Administrator, carried through drastic measures for stimulating the production of fuel, regulating shipments and distributing supplies. On March 21 the Federal Control Act placed the management of all the railways in the country in the hands of the Government during the War, and for a period after its close. W. G. McAdoo, Secretary of the Treasury, was made director-general of the railways; later Walter D. Hines, an experienced railway man, succeeded him. One of the most serious needs of the times was a merchant fleet adequate to carry across the Atlantic the army and its supplies. The Government undertook the great task of improvising such a fleet, and vast construction was authorised in both steel and wood.

*War Activities at Home.*—At once after the declaration of War the American people through official and unofficial channels gave support by civilian service and money contribution. Among the multifarious public agencies was a Committee on Public Information, of which George Creel, journalist, was chairman, which kept up a lively system of publicity aided by the National Board for Historical Service. A Censorship Board censored all communications—mail, cable, radio—passing between the United States and foreign countries. As early as Aug. 29 1916 a Council of National Defence was created by Act of Congress. Under it were created numerous special organisations. The Council of National Defence appointed a Women's Committee to co-ordinate the patriotic work of the women throughout the country. The Advisory Commission of the Council of National Defence created a Committee on Transportation and Communication. A Railroad War Board undertook to secure unity of operation among all the railways, to subordinate private interests and to eliminate competition. Important coastwise steamship lines were added to this system. The four large express companies were combined under the name American Railway Express Company. In 1918 the Government assumed control of telegraph, telephone, marine cable systems and radios. Many scientists were engaged in research throughout the country under the National Research Council. Commerce also was regulated.

By the Espionage Act of June 15 1917 the President was empowered to control exports, and he created a Bureau of Export Licenses and a Trade Board. A list was prepared of firms throughout the world with whom Americans should not

trade. The Government formally took charge of all foreign trade Feb. 15 1918, and seized all German ships interned in U.S. ports and ships under the Dutch and other neutral flags.

Samuel Gompers, president of the American Federation of Labour, co-operated in organising a Committee on Labour, and a Mediation Commission was appointed. A National War Labour Board (April 9 1918) acted throughout the country as a kind of "supreme court" to settle labour disputes. For the recruiting of essential labour and directing it into necessary industries a U.S. Employment Service was created.

Several private war agencies were established. Chief among these were the American National Red Cross, which was to be found wherever there was fighting, sickness, suffering or starvation; the Y.M.C.A.; Y.W.C.A.; Knights of Columbus (Catholic); Salvation Army; Jewish Welfare Board; American Library Assn. and War Camp Community Service.

*Enemies in the United States.*—While the people of the United States were practically a unit in favour of a vigorous prosecution of the War, a few, chiefly foreign-born or sons of foreign-born, were opposed to the War or more often to the nations in concert with which, and partly for whose salvation, the United States was fighting. Ever since 1914 the country had been irritated and aroused by a series of illegal, violent and often murderous acts which were traced to German and Austrian agents. Such were determined efforts to blow up the international bridge at Vanceboro, Me., and the locks of the Welland Canal, Ont. Bopp, German consul-general at San Francisco, was convicted and imprisoned for aiding German vessels in the Pacific in defiance of neutrality laws. Rintelen (after the War specially rewarded by the German Govt.) was sent to the Federal Prison at Atlanta for aiding in placing bombs on outgoing vessels with intent to destroy them. In 1910 Eugene V. Debs, presidential candidate four times of the Socialist party, was sentenced to ten years' imprisonment for advising men not to enlist. Victor Berger, member of Congress from Wisconsin, was convicted and sentenced for disloyalty, then re-elected to Congress, which refused to seat him.

The I.W.W. took advantage of the general confusion to engage in a campaign of disturbance and violence in the west; as many as 97 leaders of that order, including William Haywood, were convicted of disloyal conduct by one court at one time. These prosecutions were supported by the Trading with the Enemy Act of Oct. 6 1917, the Espionage Act of June 15 1917 and the Act of April 18 1918, relating to alien enemies. Several thousand German and Austrian citizens who were believed to be dangerous were interned. Two pro-German editors were punished for disloyal utterances in a German-American paper. These prosecutions against American-born citizens, naturalised citizens and unnaturalised foreigners continued for two years after the end of hostilities. On Dec. 25 1921 President Harding commuted the sentences of Debs and 23 others who had been convicted under the Espionage Act, but a number of persons still remained in jail under sentences for disloyal action.

*The Navy.*—Beginning with patrol work on the American coast as soon as War was declared, the activities of the U.S. Navy extended to co-operation with the British and French in the hunting down of submarines and the protection of convoys and in the laying of the North Sea mine barrage, extending from the Orkneys to Norway. The American Navy had some part in blockading the Austrian coast of the Adriatic, and it participated in maintaining that Allied command of the sea which in the end was fatal to Germany. By a remarkable convoy system over 2,000,000 troops were carried safely 3,000 m. overseas to France. In this work the utmost secrecy was necessary. In June 1917 a few cruisers and transports were provided and the first troops sent across. At intervals vessels assembled and sailed on definite routes under the protection of destroyers. According to the report of the Secretary of the Navy (1920), 911,047, or nearly half of the American troops, were carried on U.S. Navy transports; the rest chiefly by the British. Not one east-bound American transport was torpedoed by the German submarines; and only three ships were sunk on their return voyage. Three small fighting ships were destroyed by the enemy.

During the campaign of 1918 efforts were made to extend the possible field of enlistment by the passage of the Man Power Act of Aug. 27. All men between 18 and 45 were required to register with a view to service if needed, and 11,000,000 were registered. By a statute of Oct. 6 1917, provision was made for a system of military and naval insurance available for all men in the service.

*The American Army at the Front, 1918.*—To the army was given the general name of American Expeditionary Force (A.E.F.). General Pershing officially reported that at the date of the Armistice, Nov. 11 1918, there were in Europe 2,071,463 American officers and men (approximately 82,000 officers). On the same date, according to figures compiled by the War Dept., the number of troops encamped in the United States was 1,634,499 including 104,155 officers, a total of 3,700,000 enrolled. Actual contact with the enemy was first established by the American troops Nov. 5 1917, at a point between Arracourt and Parroy. During the year 1917 the transport and supply service was perfected, Bordeaux and other French ports having been assigned by the French Govt. as American bases. The rail communication to the front was improved and troops as they arrived were drilled and organised. The military errors of the Civil War and the Spanish War were not repeated. No civilians received commissions to command large bodies of troops. In theory no soldier was sent under fire unless he had been trained in trench and shock warfare, though many green troops were put into the front line in the crises of the campaign. The intention of Marshal Foch was to use the Americans to reinforce the Allied armies. General Pershing, supported by President Wilson, insisted that the American Army should be operated as a unit subject to the supreme command of Foch (March 28); this arrangement was accepted also by the English.

The first offensive against the Germans was on May 28, when Cantigny was captured by the Americans. From that time on to the end American troops were on the firing line. Belleau Wood was taken by them on June 11. Next day American airmen made their first hostile ascent. On July 15 the Germans began their last desperate attempt to reach Paris and were stopped by the French and Americans who tenaciously clung to Château-Thierry. A small American detachment was sent also to the Italian front. During Aug. the Germans were steadily giving ground. From Sept. 11-3 the Americans, operating alone, broke the Saint-Mihiel salient and drove out the Germans, capturing 443 guns and 16,000 prisoners. More troops were steadily reaching the front. From Sept. 26 to Nov. 11 the army took part in the heavy fighting of the Meuse-Argonne campaign. These operations terminated in the capture of Sedan, which (Nov. 6) broke the German rail connections and led to a request next day for an armistice. In these operations the casualties, to Nov. 11 1918, were as follows: killed in action, 35,556; died of battle wounds, 15,130; died of other wounds, 5,669; died of disease, 24,786; total deaths, 81,141; wounded, 179,625; missing, 1,160; prisoners, 2,163; total casualties, 264,089.

The fierce campaign of 1918 was the final effort of the Germans. No one can say positively that the American Army in the field was the chief element that insured victory; but there is not a doubt that the triumphant success in raising and transporting incessantly troops, provisions and supplies was to the German mind convincing and disheartening evidence that the Govt. and the people of the United States, with all their power and potentiality, would stand by the Allies indefinitely. On Nov. 11 1918, by the Armistice in which the American armies shared, the Germans admitted their defeat and at once began to evacuate the occupied regions and also portions of their own national territory.

*Rehabilitation in America, 1919.*—The task of post bellum economic adjustment was long and costly. At the end of the War the Federal Govt. by means of War statutes was controlling the food supply and its distribution, manufactures, the coal supply and shipments, railways, telegraphs and telephones, foreign commerce and shipping. It took over the property of aliens through an Alien Property Custodian. It settled conditions of interstate labour and of labour in other fields. For foreign com-

merce there was still a Shipping Board, an Emergency Fleet Corporation, a War Trade Board and a War Finance Board. Two million American soldiers were overseas and wanted to come home as soon as possible. The United States spent on the War about \$35,500,000,000, including \$9,500,000,000 lent to the Allies. Expenditures after peace came continued on a scale far beyond any previous experience of the country.

In the course of six months after the Armistice, about two-thirds of the troops were brought back, leaving behind them enormous stores, large parts of which were sold at heavy discounts to European Governments. General Pershing, the only U.S. military man of high rank whose achievements caught the public eye, received the reward of the permanent rank of general. In Sept. 1919 the American Legion, incorporated by Act of Congress, was formed to look after the interests of the ex-soldiers. By 1920 the only American troops left in Europe were an Army of Occupation on the Rhine of about 17,000.

*The Election of 1918.*—The Armistice came a few days after the State and Congressional elections of the autumn of 1918. The War was a national war. Enlistments, whether volunteer or by draft, had no relation to politics. Nobody paid any attention to the party affiliations of officers or men or civilian administrators and aids. Nevertheless, a few days before the elections, Oct. 15, President Wilson issued a circular letter urging the voters to return a Democratic majority to the Senate and the House; because, if the Republicans were successful, it would be considered an imputation upon the President. The warning was in vain: the result of the election made the new House decidedly Republican and the Senate Republican by two votes. It was apparent, therefore, that the Administration in making the necessary adjustments after the War must take into account the preponderant opposition in both Houses of Congress.

Throughout the year 1918 the influence of Theodore Roosevelt was manifestly growing. He was by his whole nature a supporter of the War. He and his four sons volunteered for service, though, as he put it with plaintive humour: "Wilson has kept me out of war." He was recognised as a Republican and the most powerful Republican. Even his strongest political enemies admitted that the party must reckon with him. As the months passed it became clear that he would be nominated by the Republican Convention of 1920 and in all probability would be elected President. But he died suddenly, Jan. 6 1919, leaving behind him a long roll of achievements and a place among the greatest of American statesmen and world figures.

*The Task of Peace.*—Three great tasks remained for the United States when active war ceased. The first was to secure a settlement and register it in a treaty or series of treaties, thus returning so far as possible to normal international relations. The second was to help in reconstituting the world and protecting it, if possible, against future wars. The third was internal reconstruction, putting an end to the special War laws and conditions and readjusting business, transportation and labour. The first two of these tasks are described in detail elsewhere (see LEAGUE OF NATIONS; PARIS, CONFERENCE OF). In addition to the suggestions made in the winter of 1916-7 President Wilson put forward on Jan. 8 1918, during the height of the War, "fourteen points" (see FOURTEEN POINTS) which he considered a necessary basis for the peace of the nations and a subsequent world agreement. These points he enlarged in later addresses to twenty-seven. The Germans afterwards asserted that the 14 points were an essential part of the Armistice.

Several changes came about in the Cabinet at the end of 1918. McAdoo resigned and was followed in the Treasury by Carter Glass, a representative from Virginia, who gave way in turn to Houston, transferred from the Dept. of Agriculture, where he was succeeded by Meredith.

*The Peace Conference.*—In Dec. 1918 President Wilson decided that he would attend the necessary Peace Conference in person, and designated as peace commissioners with himself four others—Secretary Lansing, Col. Edward M. House of Texas (his most intimate friend and political adviser), Gen. Tasker Bliss of the army, and Harry White, formerly minister to France.

These commissioners were not confirmed by the Senate; only one of them was a Republican, and not one was a member of either the Senate or the House. To Republicans it seemed that the President meant it to be a Democratic peace as well as a Democratic war.

In the Peace Conference of 1919 President Wilson, as representative of the richest and most powerful nation in the world, became one of the representatives of the four Great Powers—Great Britain, France, Italy and the United States—who engineered the treaty. He had, and used, the opportunity to draw up a League and Covenant which was a crystallisation of long-debated suggestions for a world confederation of states. President Wilson was so interested in the project for the League of Nations that when he found the French were not ready to adopt such a plan without some guarantee of protection, he signed a treaty of alliance between the United States, France and Great Britain, pledging the United States to join in war in case of invasion of France by Germany.

*American Action on the Treaty, 1919.*—No one familiar with the temper of Congress and of the American people should have supposed that such a treaty would be ratified. President Wilson returned home for a short stay (Feb. 24 – March 4) defending the general terms of the treaty and the Covenant of the League of Nations. On his return to Paris, he reversed decisions made in his absence by Col. House; and thereafter the close co-operation between the two able men diminished. On June 28 1919 Wilson and his four commissioners signed for the United States the formal Treaty of Versailles, including the Covenant of the League of Nations, which was so interwoven into the text of the treaty that it was impossible to ratify one without the other. Upon one of the subjects covered by the territorial adjustments of the treaty in which the American people felt a deep national interest—the continued occupation of Shantung by the Japanese—the President reluctantly gave way and consented to its retention by the Japanese, in spite of the general adverse opinion in the United States.

The treaty had many powerful supporters among all parties, particularly ex-President Taft, the League of Free Nations Association and the League to Enforce Peace, in which A. Lawrence Lowell, president of Harvard University, was the leading spirit. The Senate was divided into strongly opposed groups. Most of the Democrats, under the lead of Senator Hitchcock, followed the President in favouring the treaty with the Covenant as it stood. A group of Republicans, headed by Senator Lodge of Massachusetts, favoured “amendments” to the treaty and “reservations” to the League, which would have maimed but not killed the two projects. Another group desired reservations that would practically destroy both. A small but implacable junto, headed by Borah of Idaho and Johnson of California, were against both the treaty and the Covenant in any form or with any reservations.

The contest ostensibly centred about Art. X of the Covenant, under which the members of the League undertook “to respect and preserve as against external aggression the territorial integrity and existing political independence of all members of the League.” The implacable group expressed fear lest the United States be drawn into foreign wars and insisted that “no American soldiers or sailors must be sent to fight in other lands at the bidding of the League of Nations.” The President, on the other hand, regarded Art. X as the heart of the whole treaty. He declined at the critical moment to accept either amendments or reservations, except certain minor alterations. After strenuous debate and by a test vote, Nov. 19 1919, the Senate refused to ratify the Peace Treaty with reservations—the vote being 55 to 39 in favour, but not the necessary two-thirds. Thus after five months’ discussion the treaty was rejected, and the United States was left in the situation of technically remaining at war with Germany and Austria though all hostilities had ceased a year before.

President Wilson believed, until the last moment, that he could force ratification of the treaty by his logic and influence. On Sept. 26 1919, while on a speaking tour through the country in favour of the treaty, he was struck down by paraly-

sis; when he rallied sufficiently to think of public business he continued to hope that he would recover. His advisers and closest friends joined in an attempt to minimise the extent of the President’s illness, though for months he was unable to see even members of his Cabinet.

The difficulty with the Treaty and the League was that both were signed in Paris by a body of so-called commissioners who represented no lawful authority except that of the President. Whether President Wilson, or the statesmen who opposed him in the Senate, had the clearer view of the state of the world and the duties of the United States, whether the opposition could have been avoided by taking counsel with a larger group of competent men, cannot yet be decided. The fundamental fact is that the opposition to the Covenant was strong enough to prevent the ratification of the treaty even with serious reservations.

On March 4 1921 Woodrow Wilson accompanied President-Elect Harding to the Capitol as the last act of his official life. He had been president for eight years, during six of which he was the undisputed leader of his party and of the nation. Up to the fall of 1919 he carried all his points. He was responsible for a group of important revenue, banking and labour laws. He had a great hold on the affections and opinions of millions of his fellow citizens, and maintained the country’s dignity in war and peace. The people stood behind him in entering the War. He supported measures for organising and transporting millions of American soldiers. For a time in Paris he was the foremost man in the world, and he succeeded in inducing foreign statesmen to accept a League of Nations. At the height of his career he suddenly lost the prestige gained as War president of the whole country, was no longer accepted by his party, and ceased to be the one man who could appeal from Congress to the people. Before illness disabled him, he had already lost his hold upon the minds of the majority of his fellow countrymen. The ex-President lived in Washington in retirement, physically unable to take any part in public affairs. He died Feb. 3 1924.

#### POST-WAR PROBLEMS

*Presidential Election of 1920.*—The peace revealed underlying elements of dissatisfaction. The soldiers received in many states a money bonus varying in amount, and demanded a similar bonus from Congress. The general public complained bitterly against the high cost of living, while many corporations continued to make War profits in time of peace. A multitude saw their incomes and expectations reduced by the fall in the purchasing power of the dollar. As the presidential election came near, the Democratic party was paralysed by internal dissensions over the Peace Treaty and by lack of the trusted leadership of the President; it had no fixed policy in foreign relations or reconstruction, and no commanding figure to put forward for the presidency.

The Republicans were rent by personal rivalries. The supporters of Gen. Leonard Wood, Gov. Lowden of Illinois and Herbert C. Hoover of California struggled against each other for the nomination. The Convention at Chicago (June 9 1920) passed them all by, and gave the nomination to Senator Warren G. Harding of Ohio. He was backed by a strong group of stand-patters to whom, however, he seems to have made no pledges as to policy or appointments. Calvin Coolidge, Governor of Massachusetts, was put on the ticket as vice-president. The Democratic Convention held at San Francisco was confronted with similar difficulties. The nomination went to Gov. Cox of Ohio, a man little known in national affairs, with Franklin D. Roosevelt, a cousin of the former president, as candidate for the vice-presidency. In the campaign for the first time women were eligible to vote in every state. The election was a complete triumph for the Republicans, who elected Harding by a popular majority of about seven millions, and an electoral majority of 404 against 127 for Cox, besides securing solid majorities in both Houses of Congress.

The presidency was thus transferred to a man little experienced in national politics, whose task it was to take over the discordant elements and build out of them a coherent policy. President Harding began his administration under favouring auspices, although several members of his Cabinet had been chosen in the face of

strong opposition from various quarters. The new President early showed tact and ability in leading his party in favour of constructive action. Within four months an epoch-making bill providing for a Federal budget system was passed under his pressure (June 9 1921). He displayed keen interest in all attempts to restore business to a sound basis and urged prompt action in the assistance of the railways. By nature conservative, he laboured to bring the country back to a state of "normalcy."

Harding's foreign policy was set on remaining outside the League of Nations, while coming to amicable understandings on all relations with foreign nations. Hence special treaties of peace negotiated with Germany, Austria and Hungary were ratified by the U.S. Senate Oct. 18 1921. Of world-wide importance was his call for a conference at Washington of the different Powers bordering on and interested in the Pacific Ocean, to discuss both questions of the Pacific and the limitation of armaments. The conference assembled Nov. 12 1921, and closed Feb. 6 1922. The nine participants were the United States, Great Britain, France, Italy, Holland, Belgium, Portugal, China and Japan. Important agreements were signed: to limit construction of capital warships; against improper use of submarines; against gas warfare; for maintenance of the status of Pacific insular possessions; and other questions involving relations with Japan and China (*see WASHINGTON CONFERENCE*).

Before Harding came to the Presidency, two constitutional amendments had crystallised some of the results of the War. The various prohibition measures passed by Congress on the ground that the use of liquor impeded the success of the War were powerful aids to the general arguments against liquor. Twenty-eight of the states had absolutely prohibited the sale of liquor; and on Jan. 16 1919, the 18th Amendment, prohibiting the manufacture, sale, transportation or gift of intoxicants (submitted in 1917) was ratified by the necessary 36 states—eventually 46 states. It went into final effect Jan. 16 1920, enforced by the Volstead Act (passed Oct. 28 1919, over President Wilson's veto), which declared all liquors containing more than one-half of one per cent of alcohol to be intoxicating and therefore prohibited (*see PROHIBITION*).

The active War patriotism and service of women, together with the votes they already enjoyed, caused Congress (June 7 1919), to submit the 19th Constitutional Amendment, annulling all sex restrictions on suffrage. It was warmly supported by the former Progressives and by President Wilson, received the ratification of the 36th state, Aug. 24 1920, and went into force Aug. 26.

*Conditions of the United States, 1921-6.*—A study of the political, social, economic and international history of the United States must take account of the extraordinary national elation following the World War. The War produced a profound and permanent effect upon the national mind. It was the beginning of an enlargement of national life in every direction. From a World War out of which Great Britain and the British Dominions and France obtained the administration of immense areas of territory under mandates subsequently confirmed by the League of Nations<sup>1</sup> the United States claimed not a single square yard; but the nation felt free to enlarge its influence in the Caribbean<sup>2</sup> and the Pacific. Hence the maintenance and enlargement of a policy of paramount interest in the three normally independent Caribbean countries—Cuba, Haiti and the Dominican Republic; hence a strengthening of the control over the isthmus states of Panama, Honduras and Nicaragua.

To carry out great national policies, the United States could call upon a population expanding from year to year beyond any experience of mankind. The total population rose from 92,000,000 (not including the Philippine Is.) in 1910 to 106,000,000 in 1920

<sup>1</sup> Under these mandates, Mesopotamia ('Iraq), Palestine, a part of the bulk of the German possessions in Africa, including Tanganyika, and most of Cameroons, and Nauru were attributed to Great Britain; Samoa was attributed to New Zealand; former German South West Africa to the Union of South Africa; and the former German South Pacific possessions (except Nauru and Samoa) to the Commonwealth of Australia. (Ed. E. B.)

<sup>2</sup> The Virgin Is. (Danish West Indies) had already been acquired from Denmark by unopposed purchase on Jan. 25 1917.

and (estimated) to about 115,000,000 in 1926. Net immigration of 818,000 in 1910 sank to 19,000 in the War year 1918, but rose in 1924 to 663,000. The wealth of the country, estimated at 187 thousand million dollars in 1912 was counted at 321 thousand millions in 1922, and still swelled in volume. Against these figures, what were such burdens as a national debt of twenty or twenty-five thousand million dollars, bearing nearly a thousand million of annual interest, besides five and a half thousand millions of state and municipal debts? Manufacturing, transportation, mining, distribution and financial business were all prosperous and profitable.

*Political Survey, 1921-6.*—Political rancour and party spirit somewhat diminished. President Harding was a man of great personal charm, and he drew into his Cabinet in March 1921, several strong men. Secretary of State Hughes had been a Justice of the U.S. Supreme Court and candidate for the presidency in 1916. Secretary of the Treasury Mellon was a rich and successful banker and financier who had never before appeared in public life. Herbert C. Hoover, Secretary of Commerce, was brought in on account of his extraordinary gift of business organisation. Henry C. Wallace, Secretary of Agriculture, was the editor of a great agricultural newspaper. James J. Davis, Secretary of Labour, was a Welsh immigrant who had grown up in a steel mill. The other members of the Cabinet were: Will H. Hays, Postmaster-General; Edwin Denby, Secretary of the Navy; John W. Weeks, Secretary of War; A. B. Fall, Secretary of the Interior; and Henry M. Daugherty of Ohio, Attorney-General.

President Harding steered the ship of state easily, though without the commanding influence of a Roosevelt or a Wilson. He stood steadfastly against a high scale of expenditure. As a Middle Western man he was especially interested in the depressed state of agriculture. His foreign policy was strong and successful. His career was broken by a very brief illness, from which he died in San Francisco Aug. 2 1923.

Vice-President Coolidge, formerly Governor of Massachusetts, a quiet unostentatious man, set up a new régime in the White House. He was always approachable, courteous and on good terms with the newspaper correspondents of Washington, who have great influence over even presidential fortunes. He proved to be also a man of strong character, who consulted those whom he trusted, and then made up his own mind and stood by his decisions. His plain common-sense mode of life, his good temper, his patience with the two Houses of Congress, his ability to get on with other men, were combined with a keen judgment in public affairs. Coolidge for the time being continued Harding's Cabinet, but later many changes were made, so that at the end of five years, Secretary of the Treasury Mellon, Secretary of Commerce Hoover and Secretary of Labour Davis were the only men left of Harding's first Cabinet.

*Investigations of Officials.*—This growth in wealth and enterprise reacted upon the Govt. where even the President's Cabinet was disturbed and dismembered by a painful series of accusations and investigations. For some years the Govt. had conserved certain oil-bearing areas of public land as a supply of oil fuel for the navy. On April 7 1922 jurisdiction over this matter was transferred from the Navy Dept. to the Interior Dept. by an order of President Harding, the purpose of which the President did not understand. Under this supposed authority Secretary of the Interior Fall leased to the Sinclair interest a large tract in the Teapot Dome district in Wyoming, and also leased one of the California reserves to Doheny, another oil magnate. For reasons never publicly stated, Doheny turned over to Fall \$100,000 in cash. These published facts led in 1924 to an investigation by a Senate Committee under the chairmanship of Senator Walsh of Montana. Secretary of the Navy Denby's part, though no corrupt relation appeared, so aroused public opinion that he was forced to resign. He was replaced by Judge Wilbur of California. Meanwhile Attorney-General Daugherty was shown to be in close relation with shady characters: a special committee of the Senate under Senator Wheeler unearthed unexplainable transactions. Daugherty refused to allow the files of his office to be examined by the Senate Committee; whereupon President Coolidge

demanding his resignation (March 28 1924). An attempt was made by Republicans to turn the tables by prosecuting Senator Walsh and his colleague Senator Wheeler on trivial and technical charges, but the Courts dismissed the proceedings. Criminal proceedings were instituted against Doheny and Daugherty, but every possible legal technicality was invoked by the defence so that two years after the trouble began neither prosecution had been brought to trial. President Coolidge took rather a neutral attitude in these proceedings, which he considered to be outside the scope of the executive power. Daugherty was succeeded as Attorney-General by Stone of New York; then Stone was placed on the Supreme Court Bench and Sargent of Vermont became Attorney-General.

*Politics and Elections.*—In the congressional elections of 1922 the Republicans retained small working majorities in both House and Senate. There was, however, a return of earlier conditions in the appearance of a small group of radical Republicans, with Robert La Follette of Wisconsin as leader, who were able sometimes to hold the balance of power between the regular Republicans and the Democrats. In 1925 this group attempted to influence the nominations for the presidency. President Coolidge's year and a half in office seemed to justify the confidence of his party; and when the Republican Convention met in Cleveland there was no rival candidate. On the first ballot the vote was Coolidge 1,065, La Follette 34 and Hiram Johnson 10. The vice-presidency offered difficulties. In the end the choice fell upon Charles G. Dawes, known to the American public through his association with the Commission of 1923, which had devised the scheme for the payment of reparations by Germany. The Democratic Convention, held in New York, was the longest and fiercest in 60 years. The vote was divided between McAdoo, former Secretary of the Treasury, and "Al" Smith, a Roman Catholic, who had won a national reputation as Governor of New York.

The Convention balloted 103 times; but neither candidate could secure the necessary two-thirds. The convention finally nominated John W. Davis of West Virginia, former ambassador to Great Britain, with Charles Bryan (brother of William J. Bryan) as vice-presidential candidate. The campaign was quiet, and the result was that in the election (Nov. 1924) Coolidge received 15,725,016 votes, as against 8,386,503 for Davis and 4,822,856 for La Follette, who gathered up many discontented Republicans and the considerable vote usually cast for Socialist and other minor candidates. La Follette, however, had only the 13 electoral votes of his own state as against 136 for Davis and 382 for Coolidge. It was a substantial Republican victory, accompanied by a Republican majority over all of 59 in the House and 16 in the Senate. Vice-President Dawes on taking his seat in the Senate for the first time (March 4 1925) seized the occasion to suggest that the procedure of that body needed reform; and that its first duty was to pass an efficient rule of closure.

*The Coolidge Administration.*—Throughout both his terms of presidential service Coolidge addressed himself to a policy of economy. He stood by the budget bill which President Harding had secured from an unwilling Congress and continued the appointment of Gen. Herbert M. Lord as chief budget officer. This reform meant simply that Congress would not begin to act on the main appropriation bills until a budget based upon the ascertained needs of all the various departments had been drawn up, totalled and submitted by the budget officials.

In 1913 the United States adopted an income tax, made possible by the going into effect of the 17th Amendment of the Constitution. During the World War the tax was raised to high rates, intended in part to transfer some of the immense War profits to the public treasury. Thenceforward that income was the largest factor in the national revenue, and was vigorously collected from individuals and corporations. The policy of the Govt. was to break down the high scale of War expenditure, to dispense with superfluous employees and so to come back to the public needs in time of peace. Several acts of Congress, begun in 1921, reduced the rate of income tax. There was a running fight between those who wished to relieve the small taxpayer and those who thought it more important to bring down rates in the large amounts. The

result was that the amount paid in income taxes which was \$1,269,630,104 in 1919 came down to \$703,962,165 in 1923 but rose to \$1,761,659,049 in 1925. By the Act of Feb. 26 1926 the rates were still further lowered; and the provision in the statute of 1924, under which the amounts paid by individuals or corporations were open to the public, was repealed.

The tariff was not a serious issue in this period. The Underwood tariff of 1913, passed by the Democrats and somewhat altered in 1916 and 1921, was repealed by a Republican majority after the inauguration of President Harding; and an emergency Act was passed (May 27 1921). It provided for penalty duties on foreign commodities that might be dumped on the United States. Soon afterwards the Republicans framed a new bill, the Fordney-McCumber Tariff, signed by President Harding Sept. 21 1922. It included a provision, never before a part of a United States statute, under which the President was to have power (informed by a Tariff Commission) to alter rates of duty if necessary to "equalise the differences in cost of production in the United States over similar articles produced elsewhere." The receipts from duties and imports, which were \$326,000,000 in 1910 and \$325,000,000 in 1920, rose to \$545,000,000 in 1925. The public debt, which for many years previous to 1919 stood at about a thousand million dollars was \$25,478,592,113 soon after the close of the War (Aug. 31 1919); but on March 31 1926 had been reduced to \$19,736,292,774, partly by selling the surplus War material, and partly by payments made out of surplus.

*Industry and Commerce.*—However much the wealth of the country increased, it was not equally diffused; and large areas of the country were far from prosperous. The rural credits banks (see FEDERAL FARM LOAN SYSTEM), established under Wilson, furnished needed capital, and the farmers from 1917 to 1919 had a guaranteed government price of \$2.20 per bushel for wheat. When that protection was taken off after the War, a group of members of Congress in both House and Senate, commonly called the Agricultural Bloc, demanded special consideration for the agriculturists. Their prices had tumbled, and agricultural land values, inflated during the War, fell back to or below antebellum prices. The cost of living and hiring farm labourers had been nearly doubled. Considerable areas of farm land, even in favoured parts of the country, stood untilled because it cost more to cultivate the crops than they would realise. This discontent was reflected in the large popular vote for La Follette in 1924. Various propositions were made by farmers' associations and sympathetic members of Congress that the Federal Govt. permanently guarantee a price for the principal staples. The South was also affected by this movement because the inroads of the boll weevil for a time greatly reduced the output. In some degree the conditions of 1885-95 were reproduced; only it was no longer East against West, so much as the farmers of all sections against the group of manufacturers and distributors wherever established.

Organised capital in banking, in manufactures, and in trade, was rolling up in this period notwithstanding the Sherman Act, the Mann Elkins Act and other measures against combinations. In spite of Federal suits and Supreme Court decisions substantially upholding Federal control, combinations and consolidations of capital went on steadily. The railways, which had been sustained during the War by the Govt., were returned to their owners in 1920. For several years, notwithstanding a great increase in passenger and freight rates during the War, they were unable to make what they thought a fair profit. Under the Esch-Cummins Act of 1920 they were allowed to retain a profit of 5½% earnings, plus one-half of one per cent to make provision for improvements chargeable to capital accounts, all excess over 6% to be evenly divided with the Government. Meanwhile the administrative commissions which had been so powerful lost prestige. The Tariff Commission was weak and disregarded. The Labour Board was unable to enforce its decisions. The Interstate Commerce Commission and the Federal Trade Commission suffered in prestige and influence from internal strains and quarrels. The special Shipping Commission, created during the War to build up a national merchant fleet, was left with a large number of vessels for which profitable business could not be found. The Supreme Court de-

cisions, under which great corporations like the Standard Oil Co. and the American Tobacco Co. were regulated, left them more prosperous than ever. The hold of the great banks and the smaller banks and bankers on the finances of the country was unshaken. Deposits in national and state chartered banking institutions in 1925 aggregated over 40 thousand million dollars.

It took some years to restore to a normal basis the external commerce and shipping arrangement of the United States. The Govt. received a large tonnage of German ships as part of an indemnity, including the great liner "Leviathan." Slowly the fleets, cargoes and passenger lists of the transatlantic lines returned to the frequency and swiftness of antebellum days. Americans in increased numbers found their way to Europe and European visitors to America. This intercourse tended to an international appreciation of other countries. In 1926 the United States reached its highest point, up to that time, in production, wealth, internal commerce, manufacturing, transportation, banking and exchange, and international trade and finance.

*Social Questions.*—Many phases of social life went through a similar exaggeration and transition. During the War the United States offered extraordinary wages in order to activate the pursuits necessary to keep up the army. This led to a general raising of the scale of wages of skilled workers, some increase for the unskilled and considerable increase in the earnings of domestic and agricultural labourers. The Labour Unions made it their business to see that no systematic reduction of wages should succeed. Fuel was especially important; the whole anthracite supply comes from a small region in Pennsylvania. In 1923 and again in 1925 came serious strikes of the miners' unions. The last one endured 170 days, and was only settled with great difficulty by a return to previous conditions.

*Prohibition.*—The most serious social question and most difficult governmental problem of this time was national prohibition (see PROHIBITION). In 1918 more than 30 states had laws on their statute books for the restriction of the liquor traffic and 28 states prohibited it outright. During the War Congress prohibited the sale of liquor to soldiers, and then to the general public. A prohibition (Eighteenth) Amendment to the Federal Constitution was easily put through Congress, was ratified by a vote of 46 State Legislatures out of 48, and became a part of the Constitution Jan. 16 1919. On Oct. 28 1919 the Volstead Act for enforcing the Amendment was passed by Congress over the veto of President Wilson. It forbade the sale or transportation of "intoxicating liquor" which was defined as any liquor which contains one-half of one per cent of alcohol. To administer this Act required a large force of officials distributed over the country. The Amendment contained a clause under which the states were to have "concurrent jurisdiction," which appears to mean that state laws might continue in force and be carried out by state courts at the same time with the Federal system. From the very beginning there was an organised system of evasion of the laws through forged or excessive permits for the manufacture of "denatured" alcohol, and alcohol for the arts. As late as 1924 about 80,000,000 gallons of whiskey, alcohol and denatured alcohol was thus released by the Government. A regular system of "bootlegging," illegal sale and transportation sprang up. It was informally countered by "high-jackers"—that is bandits who seized bootleggers' supplies and carried them off by force, knowing that they were not likely to be followed by legal proceedings. An organised marine bootlegging trade placed a line of foreign sailing craft and steamers just outside the three-mile limit of the United States, whence they supplied the markets of the adjoining coasts.

The United States entered into treaties by which Great Britain and other nations agreed that vessels carrying their flags might be captured within that distance from the U. S. Coast which can be traversed in one hour by the vessel suspected of endeavouring to commit an offense. This might possibly be as much as thirty nautical miles. Within the United States large numbers of otherwise law-abiding persons bought and sold or gave away bootleg liquor, and the difficulties of executing the law are shown by the figures of national enforcement. In one fiscal year (1924-5) 20,000,000 gal. of distilled and fermented liquors were seized;

77,000 persons were arrested; 50,000 criminal cases were entered against bootleggers; 35,000 pleas of guilty were entered and 38,000 convictions were obtained. A national law regulating the traffic in habit-forming drugs was enacted May 26 1922.

The chief unofficial agency for the enforcement of the law was the Anti-Saloon League, which made it its business to back up prosecutions and to keep the public informed. The law was denounced, and disregard of the law was defended by a considerable number of men and women of repute and influence; but Congress continued to make the necessary appropriations and to refuse all propositions to modify the enforcement of the law, with which the Supreme Court declined to interfere.

*National Defence.*—A remarkable phenomenon connected with the War was its effect upon the minds of those who served in the army and navy. The dangers, the hardships, the sufferings, the tortures of trench and hospital life were such that hardly any "service man" showed inclination to tell of his experiences or to encourage war. The armies were returned and disbanded as fast as possible; but a demand was made at once by soldiers and officers for some immediate acknowledgment of their sufferings and services. The Government attempted to head off this movement, first by an elaborate system of life insurance during the War with the privilege of continuing afterward, then by money bonuses, passed by a number of the states. The Federal Govt. instituted an elaborate rehabilitation system for training wounded or otherwise injured men in some pursuit in which they could earn their own living. The Govt. also provided hospitals and care for sick and disabled soldiers. Provision was made for special privileges of allotting government land in favour of ex-soldiers. On Sept. 20 1922 a bonus bill was defeated by President Harding's veto. On March 18 1924 a Federal bonus was enacted by a large majority vote in Congress, and President Coolidge allowed it to become law.

Notwithstanding the experience of the United States in 1917, when it declared a war without any mobile army, strong pressure was put on Congress to reduce the regular army. By an Act of Feb. 12 1925 the force of the regular army was set at 125,000 enlisted men and 7,953 enlisted men of the Philippine Scouts. A drive was directed against the system of training young men in summer camps, so that they might be available as officers if needed sometime in the future. Most of the veterans were interested in the American Legion, the most widely distributed society of service men; and that body had considerable influence in the matter of legislation for ex-soldiers.

Another serious controversy relating to defence came to a head in 1925 over the air service. The great dirigible "Shenandoah" was wrecked by a storm in Sept. 1925, the commander, Lansdowne, and thirteen men being killed. The wreck called public attention to the state of air defence. Col. William Mitchell, ignoring military law and custom, made a public attack upon the whole air service, insisting that it should no longer be divided between the army and navy departments, but should be a third separate branch of national defence. He was court-martialled, convicted, suspended for five years and allowed to resign and leave the service.

*International Relations.*—The foreign affairs of the United States are always much affected by changes in party and in personnel. President Coolidge, accepting the resignation of Charles E. Hughes from the Department of State, appointed as his successor (Feb. 1925) Frank B. Kellogg, previously a Senator and Ambassador to Great Britain. To the powerful chairmanship of the committee on foreign relations, after the death of Henry Cabot Lodge of Massachusetts, who had been head of the opposition to the ratification of the League and Covenant, succeeded William E. Borah of Idaho (Dec. 1924), the famous free-lance of the Senate. A great improvement in the conduct of foreign relations was introduced by the Rogers Act, which took effect July 1 1924, under which the consular and diplomatic services were merged and the policy of training young men with the prospect of life-long service was entered upon.

The general policy of the United States towards other nations was much affected first of all by changes in international trade caused by the disruption of the World War; then by the refusal

of the Senate in 1919 to approve the Versailles Treaty and further by a strong popular opposition to any formal relation with the League of Nations. A treaty with Germany (June 28 1919) formally restored peace, provided for commerce and arranged for an adjustment of claims. A similar treaty was made with Austria under date of Sept. 10 1919. Turkey, on entering the War in 1914, declared that the capitulations were no longer in effect. The American administration nine years later accepted that policy in the American Lausanne Treaty dated July 24 1923. But a strong protest was made by friends of the Armenians and others in America, and down to 1926 ratification by the Senate had not been obtained.

*Immigration.*—An important question, partly social and partly international, was that of immigration, which went through a new phase because of the rush of people from other parts of the world as soon as the war conditions were cleared up. Complaint was made that in the previous two decades the greater part of the immigrants came from southern and eastern Europe, and was made up of persons who were not by tradition and inheritance of the same type as most of the previous immigrants. Several changes were made in 1918 and at other dates so as to reduce the number of undesirables; and by the Act of 1924, a permanent quota system was enacted, based on 2% of the number of nationals of that country shown to be in the United States by the census of 1890. This made a total of about 165,000 permissible each year from all countries, besides about 150,000 transient visitors. Unrestricted immigration from Canada and Mexico and some other sources brought the total immigration in 1924 and 1925 up to about 300,000, out of which should be taken about 100,000 emigrants, leaving a total permanent addition of about 200,000 annually.

*Reparations.*—The United States was no party to the provisions of the Versailles Treaty providing for German reparations, particularly to France, and the payment of an indemnity by Germany. However, an American force of occupation was left in the Rhine belt, the costs of which amounted to about \$200,000,000 and were to be paid by Germany. In 1921 Germany did not pay the stipulated sums to the Allies and therefore the French occupied the Ruhr Valley. The United States suggested a commission, which, headed by Charles G. Dawes (later Vice-President of the U. S.), succeeded in working out a scheme (1924) that was acceptable to France, Great Britain and Belgium, for a method of payment secured by a lien on German railways and factories. Financially the importance of the Dawes plan to the United States was that it cleared the way for considerable investments of private capital in German municipal and corporate securities.

*General Foreign Relations.*—Among the incidents of foreign relations since the War has been the recognition of various new countries created by the Treaty of Versailles: Poland, Latvia, Lithuania, Estonia, Finland, Czechoslovakia, Yugoslavia, Hungary and the enlarged Rumania. In 1924 the United States received Prof. Timothy A. Smiddy as minister from the Irish Free State. The British Govt. consented to the appointment of a direct Canadian representative at Washington, and in 1924, a diplomatic agreement was made between the United States and Canada as regards halibut fishing, for which, however, the United States insisted upon a formal approval by the British Government. This was granted in due course.

The last American troops were withdrawn from Germany in 1923. Meanwhile a joint commission on German claims was far advanced in its task. A troublesome difficulty was that a treaty with Prussia, entered into in 1828 and assumed in 1871 by the German Empire, entitled German citizens in case of war to nine months to dispose of their property in the United States and leave the country. Instead, all discernible property of Germans, and particularly of German corporations, was seized at the beginning of the War and placed in the hands of a Custodian of Enemy Property. A group of valuable German patents were turned over, for a very small payment, to American manufacturing chemists. Seven years after the end of the War the question of the legal ownership of those patents was still unsettled.

*Allies' Debts.*—A very serious and difficult issue was that of the sums lent by the United States to foreign governments during the War, aggregating nine and a half thousand million dollars. Without those enormous advances the Allies would have broken down economically before an American Army could have been placed in Europe. Nearly all the allied European countries shared in these advances. For several years interest accumulated, until, at the end of 1922, the total principal was ten thousand million dollars and the accumulated interest one and a half thousand millions more. This enormous sum was funded in United States Govt. bonds placed at about four per cent interest, mostly in American hands, upon the same footing as other obligations of the government. The interest was paid by the U. S. Treasury. In 1923 the first important adjustment of the debt was made by an agreement with England (Feb. 28 1923). The whole amount of the principal and interest then due was funded at \$4,000,000,000 to be paid in annual instalments beginning with 23 millions a year and increasing, until in the sixty-second year the debt and accruing interest would be extinguished. Similar settlements were made with Finland and other small nations. The obligations of Armenia and Russia were practically written off.

Negotiations followed with other countries and a settlement was made with Italy (Nov. 1925), ratified (April 1926), to pay \$5,000,000 a year for five years, and thereafter rising payments for 57 years. The principal was reduced from a nominal value of two thousand million dollars to a present value at 5% of £430,000,000, the very low rate of interest on long-deferred payments being thus equivalent to a reduction of about one-half the debt. In April 1926, following an unsuccessful visit of a French debt commission to the United States in Sept. 1925, a settlement was finally arrived at with France.

The total amount of the French indebtedness to be refunded, after a cash payment to adjust the sum to round figures, was declared to be \$4,025,000,000, and the repayment of this amount with interest was spread over 62 years as in the other war debt settlements. The total sum to be received by the United States under this agreement amounted to \$6,847,674,104, being an increase of approximately \$627,000,000 over the previous French offer made by M. Caillaux, and there was no "safeguard" clause as had been previously demanded.

Comparing the French settlement with those of Great Britain and Italy, the figures worked out as follows: Great Britain's agreement discounted represented slightly over 80% of her total obligation, France's approximately 50% and that of Italy 26%. The House of Representatives voted approval June 2, but ratification by the Senate was deferred pending the action of the French legislature. The various agreements made to the end of April 1926 left only \$295,000,000 unfunded war debts to the United States, including \$193,000,000 owing by Russia. In nearly all cases the period of payment is so long and the interest so low that the settlements involve payment at the value of from one-quarter to over three-quarters of the original advances by the United States.

*Latin America.*—With Latin America the United States in the main enjoyed peaceful relations. The long-standing question over the Isle of Pines was adjusted by a treaty (March 13 1925), under which the title of Cuba was acknowledged. At the request of Chile and Peru President Harding agreed in 1922 to arbitrate the obstinate dispute over the ownership of the Tacna-Arica region. After Harding's death President Coolidge took up the task and rendered his decision (March 4 1925) to the effect that the delayed plebiscite of the inhabitants should now be taken; and General Pershing was made the head of a commission to preside over this process. Chile objected, and towards the end of 1925 it seemed doubtful whether or not the award would be carried out. (See TACNA-ARICA.) With Mexico relations became strained by a dispute over the application of the new Mexican constitution of 1917 under which aliens were forbidden to hold lands or concessions. Mexicans claimed that this was in accord with the practice of several states in the United States. In 1925 Secretary Kellogg protested against the attitude of Mexico as unfriendly and declared that the Govt. of Mexico was on trial before the world.

In March 1926 a financial understanding was reached. The United States was also concerned in the outbreak of anti-foreign feeling in China and her representatives took part in a conference at Peking in Oct. 1925 upon questions relating to the withdrawal of the foreign limitation on the laying of tariffs by the Chinese Government. (See CHINA.)

**The League of Nations.**—After the refusal of the United States to ratify the Treaty of Versailles or to take part in the League of Nations, no official relations with the League were established. However, large numbers of American citizens were interested in the work of the League and some of them were appointed to advisory committees in which, however, they did not represent the American Government. Eventually the United States consented to appoint official delegates or "observers" to commissions on the Opium Traffic and other matters, instituted by the League and operating in its headquarters in Geneva. The United States became a party to treaties with regard to the white slave trade and other matters, drawn up by the League, but to take effect for only such countries as might ratify them. Gradually even the warm friends of the League accepted the conviction that it was useless for the time to urge participation in the League by the United States.

**The World Court.**—Down to 1914 the International Court at The Hague, founded in 1899 and strengthened in 1907, was in being and rendered occasional decisions. It was, however, entirely ignored by the contending parties in the six large wars that broke out from 1900 to 1914 and after the War it remained ineffective. Elihu Root, who had a share in framing the court, came forward in 1920 as the leader of an unofficial group of experts in international affairs, to propose a new world court with wide powers and jurisdiction. An advisory committee of jurists sat at The Hague and drew up a plan for a Permanent Court of International Justice. The League of Nations modified the project but established the Court (Dec. 1920) and chose the judges (Sept. 1921). (See PERMANENT COURT OF INTERNATIONAL JUSTICE.) The United States had no official relation with the Court; but the force of American public sentiment for a World League concentrated on a proposition for qualified entrance of the United States into the World Court.

This was warmly urged by President Harding and later by President Coolidge. Senator Borah, Senator Hiram Johnson of California and others strongly opposed. The progress of the movement was checked by a proposal, originally drawn by a group headed by Professor J. T. Shotwell of Columbia University and the Carnegie Endowment, who desired to enlarge the jurisdiction of the World Court and give it a compulsory character. The League of Nations modified this proposal into the so-called Geneva Protocol, which was unanimously approved by the Assembly of the League of Nations (Sept. 1924), and sent for ratifications by the nations of the world. Strong opposition was made in the United States on the plea that the Court was to decide whether a controversy was justiciable, and could assert jurisdiction over all nations and also arbitrate regarding nations, even if not members of the League of Nations. Great Britain declined to accept the compulsory jurisdiction and the whole plan fell to the ground.

This set-back left the statute constituting the World Court intact, and great pressure was exerted upon the U.S. Senate to take part in the World Court; it was urged by President Coolidge and Secretary Kellogg. On Jan. 27 1926 the Senate, by a majority of 76 to 17, voted the adhesion of the United States to the Court, with several important reservations: the United States should not be bound by advisory opinions or be subject to any obligatory jurisdiction; should participate in the election of the judges; might withdraw at its will; and no case involving the United States was to be submitted without its consent. If all the 50 or more nations that are members of the League of Nations assent to these conditions, the United States becomes so far forth a participant in a world tribunal for the settlement of international disputes and difficulties, while at the same time steadfastly disavowing any official connection with or responsibility to the League of Nations.

**The 69th Congress.**—The first session of the 69th Congress adjourned July 3 1926, its most important measures being the passage of Secretary Mellon's revenue bill which is estimated to have lightened the tax burden by \$350,000,000, and the action of the Senate in voting the adhesion of the United States to the World Court with reservations. At the date of adjournment a Senate committee was investigating the expenses of candidates in recent primary contests for the Senate.

## II. NATIONAL FINANCE AND WEALTH

### THE PUBLIC FINANCES

The dominating feature in Federal public finance since 1910 has been the financing of American participation in the World War with the subsequent readjustments necessary for returning to peace conditions. Although several significant alterations and innovations in the fiscal system had their origin in the pre-War period, 1910-6, it was the necessity for war expansion or for post-War contraction that made most of these changes important. For example, income taxation had its beginnings in the tariff Acts of 1909 and 1913, but it was due primarily to war experience that it rose to its present pre-eminent position in the revenue system. Similarly, the Federal Reserve System had begun operation in 1914, but the use of the Federal reserve banks as fiscal agents of the Government was a war development. And it was the need for retrenchment after the War that brought about the adoption of the executive budget, a measure which had been steadily advocated by successive administrations since 1910 or thereabouts.

*Public Debt.*—Although taxation was used to an unprecedented extent in financing the participation of the United States in the World War, it was necessary to borrow the greater portion of the required revenues. Four classes of interest-bearing obligations were authorised and issued: (1) Treasury certificates of indebtedness, with maturities not exceeding one year; (2) Treasury notes, with maturities from one to five years; (3) bonds, with maturities exceeding five years; and (4) war savings certificates, with maturities not exceeding five years. All were issued at not less than par except war savings certificates, on which interest was discounted in advance.

The Treasury was placed in funds through the issue of short term Treasury certificates of indebtedness, and from time to time outstanding certificates were funded into loans, discharged from tax receipts or replaced by new issues. Five war loans were issued during the War and post-Armistice periods. The War Loan Organisation, directed from the Treasury and centred at the Federal Reserve Banks, with associated Liberty Loan Committees formed in every part of the country, conducted the selling campaigns. The results are shown in table below.

The peak of the War debt was reached on Aug. 31 1919, when the gross amount outstanding stood at \$26,594,267,878. Congress, in the Victory Liberty Loan Act (March 3 1919), provided for definite and systematic discharge of the permanent debt through provision for the cumulative sinking fund, effective on July 1 1920, and through reaffirmation of directions to apply to domestic debt reduction any repayments of loans to foreign governments. The Federal budget is balanced annually on such basis. There remained the problem of the temporary or short-dated debt. Many of the maturities came at inconvenient times and in inconvenient amounts. In order to render this short-dated debt more manageable and to arrange maturities on dates and in amounts that could be discharged without undue strain the Treasury entered on a refunding programme. It resorted to issues of Treasury notes in moderate amounts from time to time, with maturities not exceeding five years. The first issue was made on June 15 1921. Other issues followed. On Oct. 16 1922, the programme was varied and a series of Treasury bonds was issued with further issues of bonds on Dec. 15 1924, March 15 1925 and March 15 1926. Each year since the War the volume of maturities has been considerably larger than the amount that could be retired, so that refunding operations have been continuously necessary and will continue to be necessary in the future. The maturities of all refunding issues are arranged for tax payment dates, and with respect to the bonds provision was made for call before maturity. Thirteen refunding issues aggregating \$6,553,693,300 have been made to March 31 1926.

Included in the short-dated debt to be discharged or refunded were the outstanding Victory notes. Approximately \$1,200,000,000 were retired through purchase for the sinking fund and other accounts, approximately \$1,500,000,000 were exchanged for other issues, and approximately \$1,800,000,000 were paid on call date or at maturity.

On March 31 1926 the outstanding debt was as follows:—

#### Interest-bearing debt—

##### Bonds:

|                               |                   |
|-------------------------------|-------------------|
| Pre-War issues                | 765,860,170.00    |
| Liberty Loans                 | 13,946,307,500.00 |
| Post-War issues               | 2,305,933,900.00  |
| Treasury notes                | 1,612,403,600.00  |
| Certificates of indebtedness  | 821,002,000.00    |
| Treasury Savings certificates | 362,218,809.60    |

Total interest-bearing debt outstanding \$19,813,725,979.60

Matured debt on which interest has ceased 20,678,670.26

Outstanding debt bearing no interest 248,365,358.49

Total gross debt \$20,082,770,008.35

Net debt, after adjustments for matured interest obligations, balance held by Treasurer of the United States, etc. \$19,736,292,774.63

\$5,369,257,859 of the interest-bearing debt matures within 5 years (before April 1 1931).

*Taxation.*—There were three notable features in the history of Federal taxation in the period 1910-26. The first was the

| Issue                                              | Amount Subscribed | Amount Allotted and Issued | Number of Subscribers (estimated) |

adoption of an income tax with progressive rates and its rapid growth to a position of pre-eminence in the revenue system. The second was the unprecedented expansion of taxation during the War, which made it possible to pay nearly one-third of the War costs, including loans to the Allies, from current revenues. The third feature was the post-War reduction in taxation, made possible by an aggressive campaign for economy in public expenditures and by the adoption of an executive budget.

Until 1913 practically all the Federal revenue had been derived from customs and internal excise duties on alcoholic beverages and tobacco. In 1910, customs duties were furnishing 50% of the total ordinary receipts of the Federal Govt., while 40% came from internal taxes on tobacco and alcoholic beverages. The ratification of the 16th Amendment in 1913 permitted the Federal Govt. to "lay and collect taxes on incomes from whatever source derived," a privilege that was immediately made use of by a provision in the Tariff Act of Oct. 3 1913. With the War came an expansion in all taxes, but the new income tax supplied the major portion of the increased revenues. By 1925, after two reductions had taken place in the maximum rates, income and profits taxes still yielded almost as much as all other sources of ordinary revenue combined, while customs duties provided only about one-seventh, and tobacco taxes less than one-tenth, of the total ordinary receipts. The following table shows the growth in importance of the income tax from 1910 to 1925.

*Relative Importance of Principal Federal Taxes, 1910-25*

(1) On warrant basis.

(2) On basis of reports of collections. Includes special taxes relating to manufacture and sale.

(3) From a 1% "excise tax" on corporation incomes. Adopted 1909.

Source: Annual Report of the Secretary of the Treasury, 1925, pp. 485, 497.

Under the stimulation of War necessity, not only were former taxes increased to maximum rates, but a multitude of new and temporary taxes came into being. In each successive Revenue Act from 1914 to 1918, both of these tendencies were illustrated. The climax came in the Revenue Act of 1918, approved Feb. 24 1919, which constituted the high water mark for tax levies in American history. Under this law, rates on personal incomes earned in 1918 began with 6% on the smallest incomes and rose to 77% (65% surtax) on net incomes of over \$1,000,000. For years subsequent to 1918, a small reduction in the normal tax was provided, which reduced the rate applicable to the highest incomes to 73%. Corporations were taxed 12% on their net incomes, 1% on their capital stock, and, under a combined War-profits and excess-profits tax, an additional amount up to 80% of the profits in excess of certain credits (based on 8% of invested capital and the rate of pre-War earnings). Estates of decedents were made taxable at rates reaching a maximum of 25%. Excise and occupation taxes were increased from the already high rates of 1917, and many new levies were made on transactions and articles of consumption.

This law was in effect until 1921, when the new Republican administration upon coming into office began an aggressive campaign to decrease expenditures in order to permit a reduction in the high taxes. The success of this economy programme was greatly enhanced by the establishment in 1921 of an executive

budget system, which permitted, for the first time, the formulation of a comprehensive fiscal programme by the administration. In spite of the increased cost of government and continued war liabilities for the public debt, disabled veterans and unliquidated War-time agencies, it was found possible to reduce taxes to some extent immediately. Accordingly, the Revenue Act of 1921 repealed the excess-profits tax on corporations (although the corporation income tax was increased as a partial offset), and the maximum rate on individual incomes was reduced from 73% (65% surtax) to 58% (50% surtax). Several of the more unpopular excise taxes were also repealed, such as, for example, duties on transportation, soda-fountain products, toilet and medicinal preparations and articles of clothing.

By 1924 the reduction in expenditures had made considerable progress, resulting in a surplus of about \$500,000,000 in ordinary receipts over expenditures chargeable against ordinary receipts. Congress found it possible, therefore, to make more extensive tax reductions in the Revenue Act of 1924. The maximum rate on personal incomes was reduced from 58% to 46% (40% surtax), while the smallest taxable incomes paid only 2%. Numerous excise duties, including taxes on telegraph and telephone messages, manufacturers' sales, drafts and checks, and admissions, were repealed in whole or in part.

In 1926 a thoroughgoing tax revision was undertaken in an attempt to devise a more scientific system. It was felt that some of the taxes, especially the excessive surtaxes, had a depressing effect upon industry, and, furthermore, were fiscally unnecessary. Accordingly, the maximum rate on individual incomes was fixed at 25% (20% surtax), while corresponding reductions were made in the lower brackets. Several taxes, including the gift tax and capital-stock tax, were repealed altogether, and reductions were made in many of the excises.

*Tariff.*—Two thorough revisions of the tariff have taken place since 1910. In 1913, the new Democratic administration supplanted the "cost of production" duties of the 1909 law with schedules designed to secure "effective competition" between American and foreign producers. There was a reduction in rates on many manufactured products, notably textiles, and the free list was extended to include some important raw materials and foodstuffs, as well as a few manufactures. A Tariff Commission was created to make researches into comparative costs of production, upon which future tariff rates could be based.

With the return of the Republican party to power in 1921, an emergency Act was immediately provided to be effective until a comprehensive tariff revision could be undertaken. There was a general increase in rates, and duties were imposed on many articles which had been on the free list. The new Tariff Act of 1922, as finally framed, reinforced and extended this upward revision of rates. A "flexible" provision was included which gave the President power to increase or decrease rates by not more than 50% of the statutory amount, as occasion demanded, but this privilege has been rarely used.

*Loans to Foreign Governments.*—The total principal amount of obligations of foreign governments originally held by the Treasury was \$10,338,058,352.20. Such obligations were acquired by the United States (1) under the authority of the Liberty bond acts which authorized the Secretary of the Treasury, with the approval of the President, to establish credits in favour of foreign governments engaged in war with enemies of the United States against cash advances made for the purpose, in general, of enabling those governments to meet commitments made in the United States in connection with the prosecution of the War; (2) under the authority of the Act of July 9 1918, which authorized the President, through the head of any executive department, to sell any surplus war supplies on such terms as the head of such department deemed expedient; (3) under the authority of the Act of Feb. 25 1919, appropriating \$100,000,000 as a revolving fund for the participation by the United States, in the discretion of the President, in the furnishing of foodstuffs and other urgent supplies to certain populations in Europe and countries contiguous thereto; and (4) under the authority of the Act of March 30 1920, which authorized the U.S. Grain Corporation,

with the approval of the Secretary of the Treasury, to sell or dispose of the flour in its possession, not to exceed 5,000,000 bbl. at such prices and on such terms or conditions as might be necessary to relieve populations in the countries of Europe or countries contiguous thereto, suffering for the want of food. The table below (taken from the annual report of the Secretary of the Treasury, for the fiscal year 1925) shows by countries the total principal amount of such obligations received by the United States and payments on account of principal thereof.

| Country                  | Total principal amount of obligations received under Liberty bond Acts | Total principal amount of obligations received for surplus supplies sold on credit under Act of July 9 1918 | Total principal amount of obligations received for relief supplies furnished on credit under Acts of Feb. 25 1919, and March 30 1920 | Payments on account of principal of obligations so received | Total net principal amount of obligations received by Treasury pursuant to Acts mentioned |

<sup>1</sup> Credit of \$1,932,923.45 allowed for loss of cargo on ship sunk by mine deducted.

*The Budget.*—The Budget and Accounting Act of June 10 1921, directed the President to submit annually to Congress a budget prepared by a Bureau of the Budget whose duties were to be performed directly under the President. By this means it is possible for the President to exercise a much more effective control than formerly over the estimates of appropriations submitted by the executive departments and officers. The first budget was submitted in 1921, for the fiscal year ending June 30 1923. By that same law, the Government accounting system was removed from the Treasury and an independent General Accounting Office was established under the Comptroller-General of the United States.

*The Federal Reserve Banks as Fiscal Agents.*—The organization of the Federal Reserve System has made a fundamental change with respect to the conduct of the fiscal business of the Government. The Secretary of the Treasury may require the

Federal reserve banks to act as fiscal agents of the United States and as depositaries of public moneys. They have been utilised in both capacities, and since the discontinuance of the independent Treasury system on July 1 1921 they have been the principal agents for the administration of receipts and expenditures, the depositary system, the public debt and paper currency changes.

*Other Agencies.*—During the War period and subsequently the operations of many governmental agencies created by Congress had more or less connection with and influence on national

finance. Mention may be made of the Federal control of railways and the post-War assistance given the carriers under the Transportation Act of Feb. 28 1920 and of the several War emergency corporations, the capital stocks of which were subscribed for by the Treasury and served as revolving funds, such as the Emergency Fleet Corp., the U.S. Housing Corp., the U.S. Sugar Equalisation Board, the U.S. Spruce Products Corp., the War Finance Corp. and the U.S. Grain Corporation. The United States subscribed to the capital stock of the Federal Land Banks, now repaid for the most part, furnished the capital for the Intermediate Credit Banks, and purchased Federal farm loan bonds when their public sale was inopportune. In 1910 a Postal Savings System was established that has received deposits aggregating \$1,295,753,979, while withdrawals have amounted to \$1,163,580,768. Deposits bear interest at 2% and may be converted into 2½% U.S. bonds.

Adherence to the gold standard has been one of the important factors contributing to the stability of the American financial structure. During the War actual payments in gold, though discouraged, were never suspended, and in 1922 the unrestricted payment of gold in the ordinary course of business was inaugurated.

Table I. below sets forth the receipts and expenditures of the U.S. Govt. on a warrant basis during the period July 1 1910 to June 30 1925 by fiscal years, classified as to ordinary receipts and expenditures, and public debt receipts and expenditures. The surplus or deficit of ordinary receipts and of total receipts are also shown for each year.

TABLE I. *Receipts and Expenditures of the United States Government by Fiscal Years from 1911 to 1925*<sup>1</sup>  
On basis of warrants issued.

<sup>1</sup> This statement does not include postal revenues and expenditures, except surplus postal revenues covered into the Treasury and postal deficiencies paid out of the general fund of the Treasury.

<sup>2</sup> Beginning with 1921, figures represent surplus or deficit after taking into account public debt expenditures chargeable against ordinary receipts.

| Fiscal year | Expenditures chargeable against ordinary receipts |                                                                              |                              |            |                       |                                  |                             |                             |                                                                           |
